**Subject:** Comments on Failure to Monetize Greenhouse Gas Emissions in the Draft Supplemental Environmental Impact Statements on Remand

**Submitted by:** Environmental Defense Fund, Institute for Policy Integrity at New York University School of Law, Montana Environmental Information Center, Natural Resources Defense Council, Sierra Club, Union of Concerned Scientists, The Wilderness Society, WildEarth Guardians<sup>1</sup>

In *Western Organization of Resource Councils v. BLM*, the U.S. District Court for the District of Montana agreed with Plaintiffs that, among other failings, the Bureau of Land Management (BLM) failed to analyze the environmental consequences of downstream combustion of coal, oil, and gas open to development under the Buffalo and Miles City resource management plans.<sup>2</sup> The Court, however, declined to find that BLM's additional failure to apply the social cost of greenhouse gas metrics to measure actual climate damages presented a "clear error of judgment," because "NEPA does not require a cost-benefit analysis *under these circumstances*."<sup>3</sup> The Court instead deferred to BLM's decision to analyze climate change impacts based on GHG emissions from the areas covered by the plans in the context of statewide, nationwide, or global data, finding that BLM's selection of emissions as a proxy by which to analyze climate change impacts deserved deference.<sup>4</sup> At the same time, the Court acknowledged that "[t]his comparative analysis necessarily will enlarge as BLM considers downstream impacts."<sup>5</sup>

In the draft supplemental EISs (DSEISs) on remand, BLM now continues to decline to use the social cost of greenhouse gases. The Miles City DSEIS does not mention the social cost of greenhouse gases at all.<sup>6</sup> The Buffalo DSEIS presents spurious arguments in Appendix D on why it need not use the metrics.<sup>7</sup> Yet neither the District of Montana's ruling nor the arguments in the Buffalo DSEIS resolve the matter. In both DSEISs, BLM has failed to adequately analyze and disclose information about the plans' actual

---

<sup>1</sup> Our organizations may separately and independently submit other comments on other issues raised by BLM in the Miles City and Buffalo the draft supplemental environmental impact statements [hereinafter DSEISs].

<sup>2</sup> 2018 WL 1475470 at \*18 (D.Mont. Mar. 26, 2018) [hereinafter *WORC v. BLM*].

<sup>6</sup> Miles City Field Office, BLM, *Draft Supplemental Environmental Impact Statement and Resource Management Plan Amendment* (2019) [hereinafter Miles City DSEIS].

<sup>7</sup> Buffalo Field Office, *Draft Supplemental Environmental Impact Statement and Resource Management Plan Amendment* at D-5 to D-7 (2019) [hereinafter Buffalo DSEIS].

environmental consequences, including the significance of the plans' resulting greenhouse gas emissions and contributions to climate change. The social cost of greenhouse gases is a tool that could be used to remedy these failures.

First, though the District of Montana deferred to BLM's decision not to use the social cost of greenhouse gases "under the[] circumstances" of the original EISs accompanying the plans, the Court also recognized the "benefits of the social cost of carbon protocol."<sup>8</sup> Therefore, even if the Court defers to BLM's decision to not apply the social cost of greenhouse gases in these DSEISs, doing so is clearly beneficial. Doing so is also straightforward, as all that is required once emissions are quantified is to multiply each year's emissions by the corresponding social cost of greenhouse gas values, discount future climate costs back to present value, and sum across all years. Because the additional information provided by the social cost of greenhouse gas protocol will "benefit" both the public and decisionmakers, BLM should execute the basic math involved (multiplication and addition) and apply the social cost of greenhouse gases.

Second, the District of Montana's ruling was limited to "these circumstances."<sup>9</sup> In particular, BLM attempted to assess the significance of the plan's upstream and direct emissions, but had not yet considered downstream emissions. As the Court acknowledged, the required "analysis necessarily will enlarge as BLM considers downstream impacts."<sup>10</sup> The downstream emissions are considerably larger than the direct and upstream emissions: in the case of the Buffalo DSEIS, for example, downstream emissions are 95-98% of total quantified emissions.<sup>11</sup> The significance of these massive downstream emissions cannot be adequately disclosed without using a tool like the social cost of greenhouse gases. Volumetric estimates or percent comparisons alone will not convey the magnitude of these plans' contributions to concrete climate damages.

Third, the District of Montana may not have fully considered all arguments in favor of using the social cost of greenhouse gases. The Court favorably recounted the decision from *High Country Conservation Advocates v. U.S. Forest Service*, but then attempted to distinguish its case from *High Country* on at least two grounds. First, the Court suggested that in *High Country*, the agency had omitted the social cost of carbon "without adequate justification."<sup>12</sup> But *High Country*'s ruling was not based solely on a failure to explain its choice, but more broadly by arbitrarily treating important climate costs as if they were worthless: "[B]y deciding not to quantify the costs at all, the agencies effectively zeroed out the cost in its quantitative analysis."<sup>13</sup> Additionally, a similar case from the District of Montana, *Montana Environmental Information Center v. Office of Surface Mining*, the Court there held it was arbitrary not to use the social cost of carbon even when the agency had presented three arguments to explain its decision.<sup>14</sup> Consequently, BLM's barebones and inaccurate explanations for why it did not use the social cost of greenhouse gases here does not excuse the failures to analyze and disclose the significance of emissions resulting from these plans —especially when, as here, BLM makes false representations, such as claiming that "it is not possible to accurately distinguish the impacts on global climate change from

<sup>10</sup> *Id.* at 18.

<sup>11</sup> Buffalo DSEIS at 3-22.

<sup>12</sup> WORC v. BLM at \*14.

<sup>13</sup> *High Country*, 52 F.Supp.3d 1174, 1192 (D.Colo. 2014). See also *id.* at 1193 & n.4 (dismissing post-hoc explanations as "unpersuasive" even if the court were permitted to consider them).

<sup>14</sup> 274 F.Supp.3d 1074, 1094 (D. Mont. 2017).

GHG emissions originating just from the planning area,”<sup>15</sup> when in fact the social cost of greenhouse gas protocol is exactly such a tool.

The second attempt in *WORC v. BLM* to distinguish *High Country* also fails. The Court noted that, in *High Country*, the agencies had arbitrarily “ignore[d] an analysis of the proposed costs of the lease modification as too speculative while including a similarly speculative analysis of the proposed benefits.”<sup>16</sup> Yet that is precisely the same arbitrary choice BLM has made here, in monetizing the plans’ alleged economic benefits but refusing to apply the social cost of greenhouse gases to disclose the significance of the plans’ climate costs. Whether or not NEPA requires a formal cost-benefit analysis is irrelevant; what matters is that, in these DSEISs, BLM continues to fail to disclose the significance of the plans’ climate effects, and inconsistently selects which effects it wants to contextualize in terms of money (economic effects) and which it does not (climate effects). Despite the District of Montana’s ruling, the DSEISs’ analyses of the plans’ impacts on climate change remain inadequate.

These comments elaborate on these arguments and explain why the social cost of greenhouse gas metrics should be used to assess the climate consequences in the Buffalo and Miles City SEISs on remand. Notwithstanding these comments’ focus on BLM’s failure to monetize climate damages, it is also important to note at the outset of these comments that BLM has also mistakenly claimed that there will be no difference in actual greenhouse gas emissions under either plan no matter which alternative action is selected.<sup>17</sup> These claims are incorrect because of errors in BLM’s analysis of substitution effects, prices, and market demand. Such errors are discussed in other comments submitted separately by various groups. A proper quantification of emissions would reveal significant differences in net emissions between the alternatives under consideration, and monetization of those different emissions would reveal the significance of the climate impacts resulting from BLM’s choices made in these plans.<sup>18</sup>

## I. BLM Must Monetize the Social Cost of Greenhouse Gases in Its DSEISs

The National Environmental Policy Act (NEPA), the statute under which environmental impact statements are required, directs agencies to fully and accurately analyze the environmental, public health, and social welfare differences between proposed alternatives, and to contextualize that information for decision-makers and the public. NEPA requires a more searching analysis than merely disclosing the amount of pollution. Rather, BLM must examine the “ecological[,]... economic, [and] social” impacts of those emissions, including an assessment of their “significance.”<sup>19</sup> By failing to use available tools, such as the social cost of greenhouse gases, to analyze the significance of emissions, BLM violates NEPA.

---

<sup>15</sup> Buffalo DSEIS at 3-15; *accord*. Miles City DSEIS at 3-16.

<sup>16</sup> *WORC v. BLM* at \*14.

<sup>17</sup> Buffalo DSEIS at 3-12, 3-13, 3-21 (“The GHG emissions . . . are the same under [both alternatives]. This is because the same RFD is used in both alternatives.”); *accord*. Miles City DSEIS at 3-12 to 3-14.

<sup>18</sup> In fact, in the Buffalo DSEIS, BLM tries to argue that it cannot use the social cost of greenhouse gas metrics because optimally the values should be applied to a calculation of net emissions, based on substitution effects in the fuel markets, and the agency claims such an analysis is “beyond the scope” of the DSEIS. D-6 to D-7. However, that kind of substitution analysis is precisely what BLM should do. BLM cannot use its failure to perform an adequate substitution analysis as a justification for its related failure to assess the significance of the plan’s contributions to climate change. Barring a proper substitution analysis, BLM should apply the social cost of greenhouse gas metrics to its estimates of the plans’ gross contributions to emissions. Such an approach would be consistent with how BLM reports economic benefits, such as income and royalties, which BLM also reports as gross totals to the regional economy or to governments, without any discussion of how, on net, fossil fuel development in the Miles City and Buffalo areas would likely offset other economic activity in other sectors or regions.

<sup>19</sup> 40 C.F.R. §§ 1508.8(b), 1502.16(a)-(b).

### ***Monetizing Climate Damages Fulfills the Obligations and Goals of NEPA***

When a project has climate consequences that must be assessed under NEPA, monetizing the climate damages fulfills an agency's legal obligations under NEPA in ways that simple quantification of tons of greenhouse gas emissions cannot. NEPA requires "hard look" consideration of beneficial and adverse effects of each alternative option for major federal government actions. The U.S. Supreme Court has called the disclosure of impacts the "key requirement of NEPA," and held that agencies must "consider and disclose the *actual environmental effects*" of a proposed project in a way that "brings those effects to bear on [the agency's] decisions."<sup>20</sup> Courts have repeatedly concluded that an environmental impact statement must disclose relevant climate effects.<sup>21</sup> NEPA requires "a reasonably thorough discussion of the significant aspects of the probable environmental consequences," to "foster both informed decisionmaking and informed public participation."<sup>22</sup> In particular, "[t]he impact of greenhouse gas emissions on climate change is precisely the kind of cumulative impact analysis that NEPA requires," and it is arbitrary to fail to "provide the necessary contextual information about the cumulative and incremental environmental impacts."<sup>23</sup> Furthermore, the analyses included in environmental assessments and impact statements "cannot be misleading."<sup>24</sup> An agency must provide sufficient informational context to ensure that decisionmakers and the public will not misunderstand or overlook the magnitude of a proposed action's climate risks compared to the no action alternative. As this section explains, by only quantifying the volume of greenhouse gas emissions, agencies fail to assess and disclose the actual climate consequences of an action and misleadingly present information in ways that will cause decisionmakers and the public to overlook important climate consequences. Using the social cost of greenhouse gas metrics to monetize climate damages fulfills NEPA's legal obligations in ways that quantification alone cannot.

### ***BLM Must Assess Actual Incremental Climate Impacts, Not Just the Volume of Emissions***

The tons of greenhouse gases emitted by a project are not the "actual environmental effects" under NEPA. Rather, the actual effects and relevant factors are the incremental climate impacts caused by those emissions, including:<sup>25</sup>

---

<sup>20</sup> *Baltimore Gas & Elec. Co. v. Natural Res. Def. Council*, 462 U.S. 87, 96 (1983) (emphasis added); see also 40 C.F.R. § 1508.8(b) (requiring assessment of the "ecological," "economic," "social," and "health" "effects") (emphasis added).

<sup>21</sup> As the Ninth Circuit has held: "[T]he fact that climate change is largely a global phenomenon that includes actions that are outside of [the agency's] control . . . does not release the agency from the duty of assessing the effects of *its* actions on global warming within the context of other actions that also affect global warming." *Ctr. for Biological Diversity v. Nat'l Highway Traffic Safety Admin.*, 538 F.3d 1172, 1217 (9th Cir. 2008); see also *Border Power Plant Working Grp. v. U.S. Dep't of Energy*, 260 F. Supp. 2d 997, 1028-29 (S.D. Cal. 2003) (failure to disclose project's indirect carbon dioxide emissions violates NEPA).

<sup>22</sup> *Ctr. for Biological Diversity*, 538 F.3d at 1194 (citations omitted).

<sup>23</sup> *Id.* at 1217.

<sup>24</sup> *High Country Conservation Advocates v. U.S. Forest Service*, 52 F. Supp. 3d 1174, 1182 (D. Colo. 2014); accord *Johnston v. Davis*, 698 F.2d 1088, 1094-95 (10th Cir. 1983) (disapproving of "misleading" statements resulting in "an unreasonable comparison of alternatives"); *Hughes River Watershed Conservancy v. Glickman*, 81 F.3d 437, 446 (4th Cir. 1996) ("For an EIS to serve these functions" of taking a hard look and allowing the public to play a role in decisionmaking, "it is essential that the EIS not be based on misleading economic assumptions"); see also *Sierra Club v. Sigler*, 695 F.2d 957, 979 (5th Cir. 1983) (holding that an agency's "skewed cost-benefit analysis" was "deficient under NEPA"); see generally *Bus. Roundtable v. SEC*, 647 F.3d 1144, 1148-49 (D.C. Cir. 2011) (criticizing an agency for "inconsistently and opportunistically fram[ing] the costs and benefits of the rule" and for "fail[ing] adequately to quantify the certain costs or to explain why those costs could not be quantified").

<sup>25</sup> These impacts are all included to some degree in the three integrated assessment models (IAMs) used by the IWG (namely, the DICE, FUND, and PAGE models), though some impacts are modeled incompletely, and many other important damage categories are currently omitted from these IAMs. Compare Interagency Working Group on the Social Cost of Carbon, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis* at 6-8, 29-33 (2010), <https://obamawhitehouse.archives.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf>

- property lost or damaged by sea-level rise, coastal storms, flooding, and other extreme weather events, as well as the cost of protecting vulnerable property and the cost of resettlement following property losses;
- changes in energy demand, from temperature-related changes to the demand for cooling and heating;
- lost productivity and other impacts to agriculture, forestry, and fisheries, due to alterations in temperature, precipitation, CO<sub>2</sub> fertilization, and other climate effects;
- human health impacts, including cardiovascular and respiratory mortality from heat-related illnesses, changing disease vectors like malaria and dengue fever, increased diarrhea, and changes in associated pollution;
- changes in fresh water availability;
- ecosystem service impacts;
- impacts to outdoor recreation and other non-market amenities; and
- catastrophic impacts, including potentially rapid sea-level rise, damages at very high temperatures, or unknown events.<sup>26</sup>

The Miles City DSEIS briefly mentions changes in temperature, sea level, and precipitation and alludes to effects on “natural and human systems,” and refers back to its original description of climate change from 2015,<sup>27</sup> but nowhere refers even qualitatively, let alone quantitatively, to the plan’s actual contributions to concrete climate effects like property loss, agricultural productivity, or human health. The Buffalo DSEIS does ever so slightly better by mentioning a few possible health effects of climate change in general,<sup>28</sup> but still does not characterize the significance of the plan’s contributions to actual, individual climate effects, like agricultural productivity or changes in energy demand.

Even a general, qualitative discussion of climate change, by calculating only the tons of greenhouse gases emitted or a percent comparison to sectoral or national emissions fails to meaningfully assess the actual incremental impacts to property, human health, productivity, and so forth.<sup>29</sup> BLM therefore falls

<sup>27</sup> Miles City DSEIS at 3-8.

<sup>28</sup> Buffalo DSEIS at 3-20.

<sup>29</sup> See *High Country*, 52 F. Supp. 3d at 1190 (“Beyond quantifying the amount of emissions relative to state and national emissions and giving general discussion to the impacts of global climate change, [the agencies] did not discuss the impacts caused by these emissions.”); *Mont. Envtl. Info. Ctr. v. U.S. Office of Surface Mining*, 274 F. Supp. 3d 1074, 1096–99 (D. Mont. 2017) (rejecting the argument that the agency “reasonably considered the impact of greenhouse gas emissions by quantifying the emissions which would be released if the [coal] mine expansion is approved, and comparing that amount to the net emissions of the United States”).

short of its legal obligations and statutory objectives by focusing just on volume estimates. Similarly, courts have held that just quantifying the acres of timber to be harvested or the miles of road to be constructed does not constitute a “description of *actual* environmental effects,” even when paired with a qualitative “list of environmental concerns such as air quality, water quality, and endangered species,” when the agency fails to assess “the degree that each factor will be impacted.”<sup>30</sup>

By monetizing climate damages using the social cost of greenhouse gas metrics, BLM can satisfy the legal obligations and statutory goals to assess the incremental and actual effects bearing on the public interest. The social cost of greenhouse gas methodology calculates how the emission of an additional unit of greenhouse gases affects atmospheric greenhouse concentrations, how that change in atmospheric concentrations changes temperature, and how that change in temperature incrementally contributes to the above list of economic damages, including property damages, energy demand effects, lost agricultural productivity, human mortality and morbidity, lost ecosystem services and non-market amenities, and so forth.<sup>31</sup> The social cost of greenhouse gas tool therefore captures the factors that actually affect public welfare and assesses the degree of impact to each factor, in ways that estimating the volume of emissions alone cannot.

#### ***Climate Damages Depend on Stock and Flow, But Volume Estimates Only Measure Flow***

The climate damage generated by each additional ton of greenhouse gas emissions depends on the background concentration of greenhouse gases in the global atmosphere. Once emitted, greenhouse gases can linger in the atmosphere for centuries, building up the concentration of radiative-forcing pollution and affecting the climate in cumulative, non-linear ways.<sup>32</sup> As physical and economic systems become increasingly stressed by climate change, each marginal additional ton of emissions has a greater, non-linear impact. The climate damages generated by a given amount of greenhouse pollution is therefore a function not just of the pollution’s total volume but also the year of emission, and with every passing year an additional ton of emissions inflicts greater damage.<sup>33</sup>

As a result, focusing just on the volume or rate of emissions, as BLM does here, is insufficient to reveal the incremental effect on the climate. The change in the rate of emissions (flow) must be assessed given the background concentration of emissions (stock). A percent comparison to national emissions is perhaps even more misleading. A project that adds 23 million additional tons per year of carbon dioxide would have contributed to 0.43% of total U.S. carbon dioxide emissions in the year 2012.<sup>34</sup> In the year 2014, that same project with the same carbon pollution would have contributed to just 0.41% of total U.S. carbon dioxide emissions—a seemingly smaller relative effect, since the total amount of U.S. emissions increased from 2012 to 2014.<sup>35</sup> However, because of rising background concentrations of global greenhouse gas stock, and because of growing stresses in physical and economic systems, the marginal climate damages per ton of carbon dioxide (as measured by the social cost of carbon)

---

<sup>30</sup> *Klamath-Siskiyou Wildlands Ctr. v. Bureau of Land Mgmt.*, 387 F.3d 989, 995 (9th Cir. 2004) (“A calculation of the total number of acres to be harvested in the watershed is . . . not a sufficient description of the actual environmental effects that can be expected from logging those acres.”); see also *Oregon Natural Res. Council v. Bureau of Land Mgmt.*, 470 F.3d 818 (9th Cir. 2006).

<sup>31</sup> 2010 TSD, *supra* note 25, at 5.

<sup>32</sup> Carbon dioxide also has cumulative effects on ocean acidification, in addition to cumulative radiative-forcing effects.

<sup>33</sup> See 2010 TSD, *supra* note 25, at 33 (explaining that the social cost of greenhouse gas estimates grow over time).

<sup>34</sup> Total U.S. carbon dioxide emissions in 2012 were 5,366.7 million metric tons (for all greenhouse gases, emissions were 6,529 MMT CO<sub>2</sub> eq.). See EPA, *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2016* at ES-6, tbl. ES-2 (2018).

<sup>35</sup> Total U.S. carbon dioxide emissions in 2014 were 5,568.8 million metric tons (and for all greenhouse gases, 6,763 MMT CO<sub>2</sub> eq.) *Id.*

increased from \$33 in 2012 to \$35 in 2014 (in 2007\$).<sup>36</sup> Consequently, those 23 million additional tons would have caused marginal climate damages costing \$759 million in the year 2012, but by 2014 that same 23 million tons would have caused \$805 million in climate damages. To summarize: the percent comparison to national emissions misleadingly implied that a project adding 23 million more tons of carbon dioxide would have a relatively less significant effect in 2014 than in 2012, whereas monetizing climate damages would accurately reveal that the emissions in 2014 were much more damaging than the emissions in 2012—almost \$50 million more. In this same way, BLM’s comparison here of the plans’ annual emissions to either national or global emissions (e.g., annual emissions from Buffalo coal development and combustion are 0.77% of global emissions;<sup>37</sup> annual emissions from Miles City coal are 0.62% of national emissions<sup>38</sup>) misleadingly suggests that the project’s contribution to climate change is static and small, while in fact a continuing stream of about 400 million metric tons per year in emissions will inflict marginally increasing damage each year as background concentrations rise. Comparing the plans’ emissions to a state, national, or global inventory reveals nothing about the significance of the project’s contributions to actual environmental impacts.

Capturing how marginal climate damages change as the background concentration changes is especially important because NEPA requires assessing both present and future impacts.<sup>39</sup> Marginal climate damages caused by this project’s additional emissions depend not just on the rate of other emissions, but crucially also on how this project adds to the background concentration of greenhouse gases, which may continue to rise even if the national or worldwide rate of emissions decreases in the short term.

By factoring in projections of the increasing global stock of greenhouse gases as well as increasing stresses to physical and economic systems, the social cost of greenhouse gas metrics enable accurate and transparent comparisons of projects with varying greenhouse gas emissions over time.

#### ***Monetization Provides the Required Informational Context that Volume Estimates Lack***

NEPA requires sufficient informational context. Yet without proper context, numbers like 0.62% of national emissions or 0.77% of global emissions will be misinterpreted by people as meaningless, as zero. Indeed, in a country of over 300 million people and over 6.5 billion tons of annual greenhouse gas emissions, it is far too easy to make highly significant effects appear relatively trivial.<sup>40</sup> For example, presenting all weather-related deaths as less than 0.1% of total U.S. deaths makes the risk of death by weather event sound trivial, but in fact that figure represents over 2,000 premature deaths per year<sup>41</sup>—

---

<sup>36</sup> Interagency Working Group on the Social Cost of Greenhouse Gases, *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis* at 25 tbl. A1 (2016) (calculating the central estimate at a 3% discount rate), [https://obamawhitehouse.archives.gov/sites/default/files/omb/inforeg/scc\\_tsd\\_final\\_clean\\_8\\_26\\_16.pdf](https://obamawhitehouse.archives.gov/sites/default/files/omb/inforeg/scc_tsd_final_clean_8_26_16.pdf) [hereinafter 2016 TSD].

<sup>37</sup> Buffalo DSEIS at 3-15.

<sup>38</sup> Miles City DSEIS at 3-16.

<sup>39</sup> NEPA requires agencies to weigh the “relationship between local short-term uses of man’s environment and the maintenance and enhancement of long-term productivity,” as well as “any irreversible and irretrievable commitments of resources.” 42 U.S.C. § 4332(2)(C).

<sup>40</sup> As California’s CEQA guidance explains, “A project’s incremental contribution may be cumulatively considerable even if it appears relatively small compared to statewide, national or global emissions.” Final Adopted Text for Revisions to the CEQA Guidelines, available at <https://perma.cc/P4S7-XAMF> [[http://resources.ca.gov/ceqa/docs/2018\\_CEQA\\_FINAL\\_TEXT\\_122818.pdf](http://resources.ca.gov/ceqa/docs/2018_CEQA_FINAL_TEXT_122818.pdf)].

<sup>41</sup> Compare Nat’l Ctr. for Health Stat., Ctrs. for Disease Control & Prevention, *Death Attributed to Heat, Cold, and Other Weather Events in the United States, 2006-2010* at 1 (2014) (reporting about 2000 weather-related deaths per year) with Nat’l Ctr. for Health Stat., *Deaths and Mortality*, <https://www.cdc.gov/nchs/faststats/deaths.htm> (reporting about 2.7 million U.S. deaths per year total).

hardly an insignificant figure.<sup>42</sup> As the U.S. Court of Appeals for the Fifth Circuit recently observed, even a seemingly “very small portion” of a “gargantuan source of [harmful] pollution” may nevertheless “constitute[ ] a gargantuan source of [harmful] pollution on its own terms.”<sup>43</sup> In other words, percentages can be misleading and can be manipulated by the choice of the denominator; what matters is the numerator’s actual contribution to total harm.

Economic theory explains why monetization is a much better tool than volume estimates or percent comparisons to provide the necessary contextual information on climate damages. For example, many decisionmakers and interested citizens would wrongly reduce down to zero the climate risks associated with 0.62% of national emissions or 0.77% of global emissions, simply because of the leading zero before the decimal place. As Professor Cass Sunstein has explained—drawing from the work of recent Nobel laureate economist Richard Thaler—a well-documented mental heuristic called “probability neglect” causes people to irrationally reduce small probability risks entirely down to zero.<sup>44</sup> People have significant “difficulty understanding a host of numerical concepts, especially risks and probabilities.”<sup>45</sup> Characterizing an annual contribution of nearly 400 million metric tons of carbon dioxide equivalent on average per year from coal production and combustion as just 0.77% of global emissions misleadingly makes the climate impacts appear vanishingly small. By comparison, by applying the social cost of carbon dioxide (about \$51 per ton for year 2020 emissions in 2017\$<sup>46</sup>), decisionmakers and the public can readily comprehend that 403 million tons of carbon dioxide emitted just in the year 2020<sup>47</sup> will generate over \$20 billion in climate damages in that year alone.<sup>48</sup>

Similarly, many people will be unable to distinguish the significance of project alternatives or scenario analyses with different emissions, or even to distinguish the 5.1 million metric tons of average annual emissions from Buffalo’s oil and gas<sup>49</sup> from the 399 million metric tons of average annual emissions from Buffalo’s coal.<sup>50</sup> As the Environmental Protection Agency’s website explains, “abstract measurements” of so many tons of greenhouse gases can be rather inscrutable for the public, unless “translat[ed] . . . into concrete terms you can understand.”<sup>51</sup> Abstract volume estimates fail to give people the required informational context due to another well-documented mental heuristic called “scope neglect.” Scope neglect, as explained by Nobel laureate Daniel Kahneman, among others, causes people to ignore the size of a problem when estimating the value of addressing the problem. For example, in one often-cited

---

<sup>42</sup> The public willingness to pay to avoid mortality is typically estimated at around \$9.6 million (in 2016\$). E.g., 83 Fed. Reg. 12,086, 12,098 (Mar. 19, 2018) (U.S. Coast Guard rule using the Department of Transportation’s value of statistical life in a recent analysis of safety regulations). Losing 2,000 lives prematurely to weather-related events is equivalent to a loss of public welfare worth over \$19 billion per year.

<sup>43</sup> *Southwestern Elec. Power Co. v. EPA*, No. 15-60821, 2019 WL 1577740 at \*22 (5th Cir., Apr. 12, 2019).

<sup>48</sup> This calculation in no way accepts BLM’s quantification of emissions as accurate or complete. In a proper cost-benefit analysis, future costs and benefits would be discounted to present value.

<sup>49</sup> Buffalo DSEIS at 3-19.

<sup>50</sup> *Id.* at 3-15.

<sup>51</sup> EPA, *Greenhouse Gas Equivalencies Calculator*. Available at <https://web.archive.org/web/20180212182940/> <https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator> (last updated Sept. 2017) (“Did you ever wonder what reducing carbon dioxide (CO<sub>2</sub>) emissions by 1 million metric tons means in everyday terms? The greenhouse gas equivalencies calculator can help you understand just that, translating abstract measurements into concrete terms you can understand.”).

study, subjects were unable to meaningfully distinguish between the value of saving 2,000 migratory birds from drowning in uncovered oil ponds, as compared to saving 20,000 birds.<sup>52</sup>

Scope neglect means many decisionmakers and members of the public would be unable to meaningfully distinguish between the climate risks of 5.1 million metric tons versus 399 million metric tons. While decisionmakers and the public certainly can discern that one number is higher, without any context it may be difficult to weigh the relative magnitude of the climate risks. In contrast, the different climate risks would have been readily discernible through application of the social cost of greenhouse gas metrics. In this example, while the difference between 5.1 million metric tons and 399 million metric tons has been obscured, in fact 399 million metric tons will cause almost \$20 billion more in climate damages than 5.1 million metric tons.<sup>53</sup>

In general, non-monetized effects are often irrationally treated as worthless.<sup>54</sup> On several occasions, courts have struck down administrative decisions for failing to give weight to non-monetized effects.<sup>55</sup> Most relevantly, in *Center for Biological Diversity v. NHTSA*, the U.S. Court of Appeals for the Ninth Circuit found it arbitrary and capricious to give zero value “to the most significant benefit of more stringent [fuel economy] standards: reduction in carbon emissions.”<sup>56</sup> Monetizing climate damages provides the informational context required by NEPA, whereas a simple tally of emissions volume and rote, qualitative, generic description of climate change are misleading and fail to give the public and decisionmakers the required information about the magnitude of discrete climate effects.<sup>57</sup>

BLM claims that it has given sufficient context to the plans’ emissions by providing percent comparisons to state, national, and global inventories, and by providing “tangible equivalencies, such as power plants and wind turbines.”<sup>58</sup> It is difficult to see how telling the public that the emissions from Buffalo’s coal development could be avoided by running 77,919 wind turbines,<sup>59</sup> or that the emissions from Miles City’s oil and gas development could be avoided by running 201 wind turbines,<sup>60</sup> provides any useful context or brings the problem of climate change “to a scale that is relatable to their everyday life . . . in an engaging way,” or in any way makes the emissions estimates less “hard to interpret.”<sup>61</sup> How is the public to assess whether the amount of emissions that would be offset by 201 wind turbines is significant or not? Similarly, telling readers that climate change will generally affect, for example, sea level, reveals nothing about the magnitude of this project’s contributions to such environmental impacts. And the many shortcomings of regional inventory comparisons have been explained above in detail.<sup>62</sup> Such figures remain abstract, lack context, and on their own are misleading. Money is a much

<sup>59</sup> Buffalo DSEIS at 3-16

<sup>60</sup> Miles City DSEIS at 3-21.

<sup>61</sup> Buffalo DSEIS at D-7.

<sup>62</sup> The Buffalo DSEIS also discusses how it has “considered the environmental consequences” of emissions by converting non-carbon gases into carbon dioxide-equivalents. D-7. Doing so in no way provides additional context to the plan’s actual climate impacts or the significance thereof. Moreover, it would be more accurate for BLM to apply the separate metrics for the social cost of methane and social cost of nitrous oxide, rather than converting them into carbon-dioxide equivalent emissions.

more “relatable,” “engaging,” and “relevant” scale for the public to understand, and monetizing the damages actually assesses the significance of project’s contributions. Despite BLM’s claim that “it is not possible to accurately distinguish the impacts on global climate change from GHG emissions originating just from the planning area,”<sup>63</sup> that is precisely what the social cost of greenhouse gas metrics do. Without this information, decisionmakers and the public are at a loss for how to understand to what extent the plans will contribute to climate damages.

#### ***Climate Effects Must Be Monetized If Other Costs and Benefits Are Monetized***

Though NEPA does not always require a full and formal cost-benefit analysis,<sup>64</sup> agencies’ approaches to assessing costs and benefits must be balanced and reasonable. Courts have warned agencies, for example, that “[e]ven though NEPA does not require a cost-benefit analysis,” an agency cannot selectively monetize benefits in support of its decision while refusing to monetize the costs of its action.<sup>65</sup>

In *High Country Conservation Advocates v. Forest Service*, the U.S. District Court of Colorado found that it was “arbitrary and capricious to quantify the *benefits* of the lease modifications and then explain that a similar analysis of the *costs* was impossible when such an analysis was in fact possible.”<sup>66</sup> The court explained that, to support a decision on coal mining activity, the agencies had “weighed several specific economic benefits—coal recovered, payroll, associated purchases of supplies and services, and royalties,” but arbitrarily failed to monetized climate costs using the readily available social cost of carbon protocol.<sup>67</sup> Similarly, in *Montana Environmental Information Center v. Office of Surface Mining (MEIC v. OSM)*, the U.S. District Court of Montana followed the lead set by *High Country* and likewise held an environmental assessment to be arbitrary and capricious because it quantified the benefits of action (such as employment payroll, tax revenue, and royalties) while failing to use the social cost of carbon to quantify the costs.<sup>68</sup>

*High Country* and *MEIC v. OSM* were simply the latest applications of a broader line of case law in which courts find it arbitrary and capricious to apply inconsistent protocols for analyzing some effects compared to others, especially when the inconsistency obscures some of the most significant effects.<sup>69</sup>

---

<sup>63</sup> Buffalo DSEIS at 3-15; *accord*. Miles City DSEIS at 3-15.

<sup>64</sup> 40 C.F.R. § 1502.23 (“[T]he weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis.”); *but see e.g.*, *Sierra Club v. Sigler*, 695 F.2d 957, 978-79 (5th Cir. 1983) (holding that NEPA “mandates at least a broad, informal cost-benefit analysis,” and so agencies must “fully and accurately” and “objectively” assess environmental, economic, and technical costs); *Chelsea Neighborhood Ass’n v. U.S. Postal Serv.*, 516 F.2d 378, 387 (2d Cir. 1975) (“NEPA, in effect, requires a broadly defined cost-benefit analysis of major federal activities.”); *Calvert Cliffs’ Coordinating Comm. v. U.S. Atomic Energy Comm’n*, 449 F.2d 1109, 1113 (D.C. Cir. 1971) (“NEPA mandates a rather finely tuned and ‘systematic’ balancing analysis” of “environmental costs” against “economic and technical benefits”); *Nat’l Wildlife Fed. v. Marsh*, 568 F. Supp. 985, 1000 (D.D.C. 1983) (“The cost-benefit analysis of NEPA is concerned primarily with environmental costs. . . . A court may examine the cost-benefit analysis only as it bears upon the function of insuring that the agency has examined the environmental consequences of a proposed project.”).

<sup>65</sup> *High Country Conservation Advocates*, 52 F. Supp. 3d at 1191; *accord*. *MEIC v. Office of Surface Mining*, 274 F. Supp. 3d at 1094-99 (holding it was arbitrary for the agency to quantify benefits in an EIS while failing to use the social cost of carbon to quantify costs, as well as arbitrary to imply there would be no effects from greenhouse gas emissions).

<sup>66</sup> 52 F. Supp. 3d at 1191.

<sup>67</sup> *Id.*

<sup>68</sup> 274 F. Supp. 3d at 1094-99 (also holding that it was arbitrary to imply that there would be zero effects from greenhouse gas emissions).

<sup>69</sup> Other cases from different courts that have declined to rule against failures to use the social cost of carbon in NEPA analyses are all distinguishable by the scale of the action or by whether other effects were quantified and monetized in the

For example, in *Center for Biological Diversity v. National Highway Traffic Safety Administration*, the U.S. Court of Appeals for the Ninth Circuit ruled that, because the agency had monetized other uncertain costs and benefits of its vehicle fuel efficiency standard—like traffic congestion and noise costs—its “decision not to monetize the benefit of carbon emissions reduction was arbitrary and capricious.”<sup>70</sup> Specifically, it was arbitrary to “assign[ ] no value to the most significant benefit of more stringent [vehicle fuel efficiency] standards: reduction in carbon emissions.”<sup>71</sup> When an agency bases a decision on cost-benefit analysis, it is arbitrary to “put a thumb on the scale by undervaluing the benefits and overvaluing the costs.”<sup>72</sup> Similarly, the U.S. Court of Appeals for the District of Columbia Circuit has chastised agencies for “inconsistently and opportunistically fram[ing] the costs and benefits of the rule [and] fail[ing] adequately to quantify certain costs or to explain why those costs could not be quantified”<sup>73</sup>; and the U.S. Court of Appeals for the Tenth Circuit has remanded an environmental impact statement because “unrealistic” assumptions “misleading[ly]” skewed comparison of the project’s positive and negative effects.<sup>74</sup>

These DSEISs monetize economic benefits similar to those highlighted in *High Country* and *MEIC*, including income, output, and government revenues, such as taxes and royalties.<sup>75</sup> The Miles City DSEIS offers no explanation for this inconsistent approach to monetizing some effects but not others. The Buffalo DSEIS tries to skirt the precedent set by *MEIC v. OSM* by claiming that taxes and royalties are

---

analysis. See *League of Wilderness Defenders v. Connaughton*, No. 3:12-cv-02271-HZ (D. Ore., Dec. 9, 2014); *EarthReports v. FERC*, 15-1127, (D.C. Cir. July 15, 2016); *WildEarth Guardians v. Zinke*, 1:16-CV-00605-RJ, at 23-24, (D. N.M. Feb. 16, 2017).

In *WildEarth Guardians v. Zinke*, while the U.S. District Court for the District of Columbia stopped short of requiring BLM to use the social cost of carbon, it issued its holding on very narrow grounds. Specifically, the court declined to side with plaintiffs that “it was arbitrary and capricious for BLM to discuss the economic benefits of oil and gas drilling without quantifying their economic costs” by using the social cost of carbon protocol. No. 16-1724, 2019 WL 1273181, \*22 (D.D.C. Mar. 19, 2019). However, the court did not hold that BLM’s acted consistently in choosing to monetize benefits without monetizing costs; rather, it held that BLM’s treatment of economic benefits was so “sparse[]” and “cursory” that the precedent established in *High Country Conservation Advocates v. Forest Service* could be differentiated. *Id.* But several important distinguishing arguments apply. First, the inconsistent treatment of costs and benefits is not the only reason why agencies should use the social cost of greenhouse gases to assess climate damages in NEPA reviews. The court never considered whether using the social cost of greenhouse gases was necessary or appropriate to fulfill the obligations and goals of NEPA: to assess a project’s actual real-world impacts, to weigh the intensity and significance of a project’s contributions to such impacts, and to give meaningful context to the information presented. Second, the court’s consideration was incomplete on the issue of inconsistent treatment of costs and benefits. It is not clear why the paltry size of the lease’s economic benefits should excuse BLM from inconsistently treating costs and failing to apply a readily available and easy-to-use tool to monetize the lease’s hugely significant climate costs. *High Country*’s ruling turned not on the size of the monetized benefits but on the inconsistent treatment of costs and benefits. Furthermore, the court overlooked other portions of the original EAs and the tiered EISs that monetized and relied on larger economic benefits to much greater extent. Thus, the court’s attempts to distinguish *High Country* do not hold up. The D.C. District Court also deferred to BLM’s so-called “reasoned explanations,” *id.* at \*23, yet failed to recognize that in *High Country*, the District of Colorado also considered and dismissed the post-hoc attempt to argue that the social cost of carbon protocol was too imprecise or controversial to use because of the range of estimates. 52 F. Supp. 3d 1174, 1192 (D. Colo. 2014). Finally, the court in *WildEarth v. Zinke* never discussed other important case law, such as *MEIC v. OSM*. Ultimately, the court instructed BLM on remand to “reassess” whether the social cost of greenhouse gas protocol would “contribute to informed decisionmaking” and ensure more accurate analysis as required by NEPA, *id.* at n.31. The court believed that “the protocol may one day soon be a necessary component of NEPA analyses,” *id.*—and, indeed, that day has already arrived.

<sup>70</sup> 538 F.3d 1172, 1203 (9th Cir. 2008).

<sup>71</sup> *Id.* at 1199.

<sup>72</sup> *Id.* at 1198.

<sup>73</sup> *Bus. Roundtable v. SCC*, 647 F.3d 1144, 1148-49 (D.C. Cir. 2011)

<sup>74</sup> *Johnston v. Davis*, 698 F.2d 1088, 1094–95 (10th Cir. 1983)

<sup>75</sup> See Buffalo DSEIS at 3-27 (monetizing \$346.3 million per year in federal revenue); Miles City DSEIS at 3-50 (\$152 million per year in income, \$733.9 million per year in output).

“economic impacts” and not costs or benefits.<sup>76</sup> There are several problems with BLM’s argument. First, in *MEIC v. OSM*, the District Court of the District of Montana dismissed this same argument as “a distinction without a difference.”<sup>77</sup> Despite BLM’s attempts to use terminology to distinguish the impacts it wants to monetize from those impacts it would prefer not to monetize, NEPA regulations group all these impacts under the same category of “effects”: economic and social impacts are listed as “effects” alongside ecological and health impacts, and all these effects must be discussed in as much detail as possible in an adequate NEPA review.<sup>78</sup> Whether an effect is a cost, benefit, or transfer, if monetization is the best way to assess that effect’s significance and contextualize the precise impacts, then monetization is the best way to comply with NEPA’s obligations.

Second, despite the paragraph disclaiming that regional economic impacts are not benefits, the rest of the DSEISs treat effects like taxes and royalties as benefits by touting them without any mention of offsetting losses that would occur in other regions or sectors. If this project causes a region or sector to gain a job and associated income, that may be a transfer or purely regional/sectoral impact to the extent it comes at the expense of a job lost in some other region or sector. But the DSEISs never mention—let alone quantify—such offsetting losses outside the plans’ particular region and sector. NEPA does not require a cramped view of impacts confined to only the immediate vicinity around a project or to only one sector of the economy. If BLM truly believes the plans will result in no economic benefit when viewed from a national perspective, it should say so clearly; instead, the DSEISs tout millions in alleged economic upside, with no mention of any offsetting downside.

Third, the DSEISs do, in fact, implicitly monetize the “social benefits” that BLM claims are missing.<sup>79</sup> Both DSEISs monetize royalties,<sup>80</sup> which are calculated based on a percentage of the fossil fuels’ market price. Both DSEIS also monetizes “output,”<sup>81</sup> which the Buffalo DSEIS defines as the “value of production.”<sup>82</sup> In a competitive market, like for coal, oil, and natural gas, the market price is typically thought to reflect aggregate willingness to pay based on social utility. Therefore, in calculating and reporting output and royalties, BLM has presented a monetized estimate of the supposed social benefits of the plans. Consequently, BLM must also use readily available tools to monetize the social costs of the coal, oil and gas development. It is arbitrary to apply inconsistent protocols for analysis of some effects compared to others, and to monetize some effects but not others that are equally monetizable.

## II. The Social Cost of Greenhouse Gas Metric Is Appropriate for Plans with Emissions of this Magnitude

The DSEISs claim that there are no “precise scientific tools” to quantify the project’s climate impacts, or “to accurately distinguish the impacts on global climate change from GHG emissions originating just from the planning area.”<sup>83</sup> These arguments are wrong. The social cost of greenhouse gas protocol is exactly such a tool to monetize the incremental climate impacts of specific projects or plans, and its use is not limited to rulemakings. Numerous other agencies have had no trouble applying the manageable range of estimates of the social cost of greenhouse gases to assess the significance of the climate

---

<sup>76</sup> Buffalo DSEIS at D-6.

<sup>77</sup> 274 F. Supp. 3d. at 1096 n.9.

<sup>78</sup> 40 C.F.R. §1508.8.

<sup>79</sup> Buffalo DSEIS at D-6. BLM’s references to “industrial efficiencies, technological advances, and time savings” are cryptic and confusing. Presumably, BLM intends to refer to the social benefits of fossil fuel development, including the benefits that come from combusting fossil fuels for productive purposes like to generate electricity.

<sup>80</sup> Buffalo DSEIS at 3-27; Miles City DSEIS at 3-53.

<sup>81</sup> Miles City DSEIS at 3-50; Buffalo DSEIS at D-2.

<sup>82</sup> Buffalo DSEIS at D-1.

<sup>83</sup> Miles City DSEIS at 3-15 to 3-16; accord Buffalo DSEIS 3-15.

impacts of their actions, including projects that are only expected to last a few years. NEPA requires BLM to use the best available science to support its NEPA analyses and the social cost metrics remain the best estimates yet produced by the federal government for monetizing the impacts of GHG emissions and are “generally accepted in the scientific community.” 40 C.F.R. § 1502.22(b)(4) Thus, the agency cannot use uncertainty as a red herring to escape its statutory obligations.

### ***Monetization Is Appropriate and Useful in Any Decision with Significant Climate Impacts, Not Just Regulations***

Though the federal Interagency Working Group on the Social Cost of Greenhouse Gases originally developed its estimates of the social cost of greenhouse gases to harmonize the metrics used by agencies in their various regulatory impact analyses, there is nothing in the numbers’ development that would limit applications to other decisionmaking contexts. The social cost of greenhouse gases measures the marginal cost of any additional unit of greenhouse gases emitted into the atmosphere. The government action that precipitated that unit of emissions—regulations, permit issuances, or project approvals—are irrelevant to the marginal climate damages caused by the emissions. Whether emitted by a leaking pipeline or the extraction process, or because of a regulation or a resource management decision, and whether emitted in Alaska or Maine, the marginal climate damages per unit of emissions remain the same. Indeed, the social cost of greenhouse gases has been used by many federal and state agencies in environmental impact reviews<sup>84</sup> and in resource management decisions.<sup>85</sup>

### ***The Social Cost of Greenhouse Gas Metrics Provides a Tool to Assess the Significance of Individual Physical Impacts***

The social cost of greenhouse gas methodology is well suited to measure the marginal climate damages of individual projects. These protocols were developed to assess the cost of actions with “marginal” impacts on cumulative global emissions, and the metrics estimate the dollar figure of damages for one extra unit of greenhouse gas emissions. This marginal cost is calculated using integrated assessment models. These models translate emissions into changes in atmospheric greenhouse concentrations, atmospheric concentrations into changes in temperature, and changes in temperature into economic damages. A range of plausible socio-economic and emissions trajectories are used to account for the scope of potential scenarios and circumstances that may actually result in the coming years and decades. The marginal cost is attained by first running the models using a baseline emissions trajectory, and then running the same models again with one additional unit of emissions. The difference in damages between the two runs is the marginal cost of one additional unit. The approach assumes that the marginal damages from increased emissions will remain constant for small emissions increases relative to gross global emissions. In other words, the monetization tools are in fact perfectly suited to measuring the marginal effects of individual projects or other discrete agency actions.

---

<sup>84</sup> For example, in August 2017, the Bureau of Ocean Energy Management called the social cost of carbon “a useful measure to assess the benefits of CO<sub>2</sub> reductions and inform agency decisions,” and applied the metric in an environmental impact statement to monetize the emissions difference of about 5 million metric tons per year between the proposed oil and gas development project and the no-action baseline, *Draft Environmental Impact Statement—Liberty Development Project in the Beaufort Sea, Alaska* at 3-129, 4-50 (2017). More generally, agencies have used IWG’s social cost of greenhouse gas estimates not only in scores of rulemakings but also in NEPA analyses for resource management decisions. See Peter Howard & Jason Schwartz, *Think Global: International Reciprocity as Justification for a Global Social Cost of Carbon*, 42 Columbia J. Envtl. L. 203, 270-84 (2017) (listing all uses by federal agencies through July 2016).

<sup>85</sup> States have used the social cost of greenhouse gases in decisions about electricity planning. See Iliana Paul et al., *The Social Cost of Greenhouse Gases and State Policy: A Frequently Asked Questions Guide* (Policy Integrity Report, 2017), [http://policyintegrity.org/files/publications/SCC\\_State\\_Guidance.pdf](http://policyintegrity.org/files/publications/SCC_State_Guidance.pdf).

Some of the incremental impacts on the environment that the social cost of greenhouse gas protocol captures—and which the DSEISs fails to meaningfully analyze—include property lost or damaged; impacts to agriculture, forestry, and fisheries; impacts to human health; changes in fresh water availability; ecosystem service impacts; impacts to outdoor recreation and other non-market amenities; and some catastrophic impacts, including potentially rapid sea-level rise, damages at very high temperatures, or unknown events.<sup>86</sup> A key advantage of using the social cost of greenhouse gas tool is that each physical impact—such as sea-level rise and increasing temperatures—need not be assessed in isolation. Instead, the social cost of greenhouse gas tool conveniently groups together the multitude of climate impacts and, consistent with NEPA regulations,<sup>87</sup> enables agencies to assess whether all those impacts are cumulatively significant and to then compare those impacts with other impacts or alternatives using a common metric.

### ***The Tons of Greenhouse Gas Emissions at Stake Here Are Clearly Significant***

BLM quantifies upstream and downstream greenhouse gas emissions from these plans, amounting to hundreds of millions of metric tons per year. But BLM refuses to take the straightforward next step of applying the social cost of greenhouse gas values to those quantified tons.

While there may not be a bright-line test for significance, the emissions BLM estimates for these plans are clearly significant and warrant monetization. This is especially true since, once emissions have been quantified, the additional step of monetization through application of the Interagency Working Group's 2016 estimates entails a simple arithmetic calculation.<sup>88</sup> It is difficult to understand how NEPA's mandate that an agency take a "hard look" at the environmental impacts of its actions can be satisfied if BLM fails to analyze and disclose to the public the impacts of the greenhouse gas emissions that it quantifies, including their significance.

In *High Country*, the District Court for the District of Colorado found that it was arbitrary for the Forest Service not to monetize the "1.23 million tons of carbon dioxide equivalent emissions [from methane] the West Elk mine emits annually."<sup>89</sup> That suggests a threshold for monetization well below what BLM estimates here. In *MEIC v. OSM*, the District Court for the District of Montana found it was arbitrary for the Office of Surface Mining not to monetize the 23.16 million metric tons, which constituted

---

<sup>86</sup> These impacts are all included to some degree in the three integrated assessment models (IAMs) used by the IWG (namely, the DICE, FUND, and PAGE models), though some impacts are modeled incompletely, and many other important damage categories are currently omitted from these IAMs. Compare Interagency Working Group on the Social Cost of Carbon, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis* at 6-8, 29-33 (2010), <https://obamawhitehouse.archives.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf> [hereinafter 2010 TSD]; with Peter Howard, *Omitted Damages: What's Missing from the Social Cost of Carbon* (Cost of Carbon Project Report, 2014), [http://costofcarbon.org/files/Omitted\\_Damages\\_Whats\\_Missing\\_From\\_the\\_Social\\_Cost\\_of\\_Carbon.pdf](http://costofcarbon.org/files/Omitted_Damages_Whats_Missing_From_the_Social_Cost_of_Carbon.pdf). For other lists of actual climate effects, including air quality mortality, extreme temperature mortality, lost labor productivity, harmful algal blooms, spread of west nile virus, damage to roads and other infrastructure, effects on urban drainage, damage to coastal property, electricity demand and supply effects, water supply and quality effects, inland flooding, lost winter recreation, effects on agriculture and fish, lost ecosystem services from coral reefs, and wildfires, see EPA, *Multi-Model Framework for Quantitative Sectoral Impacts Analysis: A Technical Report for the Fourth National Climate Assessment* (2017); U.S. Global Change Research Program, *Climate Science Special Report: Fourth National Climate Assessment* (2017); EPA, *Climate Change in the United States: Benefits of Global Action* (2015); Union of Concerned Scientists, *Underwater: Rising Seas, Chronic Floods, and the Implications for U.S. Coastal Real Estate* (2018).

<sup>87</sup> 40 C.F.R. § 1508.27(b)(7) (explaining that actions can be significant if related to individually insignificant but cumulatively significant impacts).

<sup>88</sup> Agencies simply need to multiply their estimate of tons in each year by the IWG's 2016 values for the corresponding year of emissions (adjusted for inflation to current dollars). If the emissions change occurs in the future, agencies would then discount the products back to present value.

<sup>89</sup> 52 F. Supp. 3d at 1191 (quoting an e-mail comment on the draft statement for the quantification of tons).

“approximately 0.35 percent of the total U.S. emissions.”<sup>90</sup> In *Center for Biological Diversity*, the Ninth Circuit found that it was arbitrary for the Department of Transportation not to monetize the 35 million metric ton difference in lifetime emissions from increasing the fuel efficiency of motor vehicles:<sup>91</sup> given the estimated lifetime of vehicles sold in the years 2008-2011 (sometimes estimated at about 15 years on average), this could represent as little 2 million metric tons per year. In a recent environmental impact statement from the Bureau of Ocean Energy Management published in August 2017, the agency explained that the social cost of carbon was “a useful measure” to apply to a NEPA analysis of an action anticipated to have a difference in greenhouse gas emissions compared to the no-action baseline of about 25 million metric tons over a 5-year period,<sup>92</sup> or about 5 million metric tons per year. BLM’s estimates of emissions from these plans vastly exceed the emissions from other projects and cases where monetization of emissions has been found useful or legally required. The direct emissions alone clearly warrant monetization, as do the substantial downstream emissions.

Under any reasonable application of the social cost of greenhouse gas metrics, the upstream and downstream emissions from fossil fuel development under the Buffalo and Miles City plans will cause billions of dollars in climate damages. Tellingly, BLM had no problem concluding that it was appropriate to monetize, for example, \$17 million in annual county revenue.<sup>93</sup> A potential climate cost of billions of dollars is also clearly significant, particularly in the context of a document the very purpose of which is to evaluate a project’s *environmental* impacts.<sup>94</sup>

#### ***Monetizing Climate Damages Is Appropriate and Useful Regardless of Whether Every Effect Can Be Monetized in a Full Cost-Benefit Analysis***

BLM’s claim that it cannot use the social cost of greenhouse gas metrics because NEPA does not require cost-benefit analysis,<sup>95</sup> is a non-sequitur. Using the social cost of greenhouse gas metrics does not require subtracting the plans’ monetized climate costs from the monetized economic benefits in a cost-benefit analysis. Rather, BLM should use the social cost of greenhouse gases because NEPA requires agencies to use readily available tools to better contextualize environmental effects, just as BLM has monetized certain economic impacts like labor income and royalties to contextualize the plans’ alleged upsides.

Monetizing one key impact still provides useful information for decisionmakers and the public even when monetizing other impacts is not feasible. The social cost of greenhouse gases enables a more accurate and transparent comparison of alternatives along the dimension of climate impacts even if other costs and benefits cannot be quantified, and “breakeven analysis” could provide a framework for making decisions when some effects but not others are monetized. Climate damages can and should be monetized even if other costs and benefits are harder to quantify or monetize and so must be discussed qualitatively. Many effects can readily be quantified and monetized, and agencies should generally do so when feasible; other effects, like water quality, are notoriously difficult to quantify and monetize, due to the geographically idiosyncratic nature of individual water bodies. Greenhouse gases, by comparison, have the same impact on climate change no matter where they are emitted, and those impacts are readily monetized using the social cost of greenhouse methodology. Regardless of whether all other

effects can be monetized, using the social cost of greenhouse gases provides useful and necessary information to the public and decisionmakers. In particular, whether or not other effects are monetized, using the social cost of greenhouse gases will facilitate comparison between alternative options along the dimension of climate change. As discussed above, different alternatives could have varying greenhouse gas consequences over time, and monetization provides the best means of comparing project alternatives along the dimension of climate change.

Moreover, analytical frameworks exist to weigh qualitative effects alongside monetized effects. NEPA regulations, for example, first state that if there are “important qualitative considerations,” then the ultimate “weighing of the merits and drawbacks of the various alternatives” should not be displayed exclusively as a “monetary cost-benefit analysis.” Nevertheless, NEPA regulations further acknowledge that when monetization of costs and benefits is “relevant to the choice among environmentally different alternatives,” “that analysis” can be presented alongside “any analyses of unquantified environmental impacts, values, and amenities.”<sup>96</sup> In other words, the monetization of some impacts does not require the monetization of all impacts.

The Office of Management and Budget’s *Circular A-4*<sup>97</sup> guidance to agencies on conducting economic analysis also provides a framework for weighing monetized and qualitative costs and benefits, called break-even analysis:

It will not always be possible to express in monetary units all of the important benefits and costs. When it is not, the most efficient alternative will not necessarily be the one with the largest quantified and monetized net-benefit estimate. In such cases, you should exercise professional judgment in determining how important the non-quantified benefits or costs may be in the context of the overall analysis. If the non-quantified benefits and costs are likely to be important, you should carry out a “threshold” analysis to evaluate their significance. Threshold or “break-even” analysis answers the question, “How small could the value of the non-quantified benefits be (or how large would the value of the non-quantified costs need to be) before the rule would yield zero net benefits?” In addition to threshold analysis you should indicate, where possible, which non-quantified effects are most important and why.<sup>98</sup>

Even without using something as formal as a break-even analysis, it is clear that monetizing climate damages provides useful information whether or not every effect can be monetized in a full cost-benefit analysis.

### **III. BLM Should Use the Interagency Working Group’s 2016 Estimates of the Social Cost of Carbon and the Social Cost of Methane**

In 2016, the IWG published updated central estimates for the social cost of greenhouse gases: \$50 per ton of carbon dioxide, \$1440 per ton of methane, and \$18,000 per ton of nitrous oxide (in 2017 dollars

for year 2020 emissions).<sup>99</sup> Agencies must continue to use estimates of a similar or higher<sup>100</sup> value in their analyses and decisionmaking. A recent Executive Order disbanding the IWG does not change the fact that the IWG estimates still reflect the best available data and methodologies.

#### **IWG's Methodology Is Rigorous, Transparent, and Based on Best Available Data**

Beginning in 2009, the IWG assembled experts from a dozen federal agencies and White House offices to “estimate the monetized damages associated with an incremental increase in carbon emissions in a given year” based on “a defensible set of input assumptions that are grounded in the existing scientific and economic literature.”<sup>101</sup> IWG’s methods combined three frequently used models built to predict the economic costs of the physical impacts of each additional ton of carbon.<sup>102</sup> The models together incorporate such damage categories as: agricultural and forestry impacts, coastal impacts due to sea level rise, impacts from extreme weather events, impacts to vulnerable market sectors, human health impacts including malaria and pollution, outdoor recreation impacts and other non-market amenities, impacts to human settlements and ecosystems, and some catastrophic impacts.<sup>103</sup> IWG ran these models using a baseline scenario including inputs and assumptions drawn from the peer-reviewed literature, and then ran the models again with an additional unit of carbon emissions to determine the increased economic damages.<sup>104</sup> IWG’s social cost of carbon estimates were first issued in 2010 and have been updated several times to reflect the latest and best scientific and economic data.<sup>105</sup>

Following the development of estimates for carbon dioxide, the same basic methodology was used in 2016 to develop the social cost of methane and social cost of nitrous oxide—estimates that captures the distinct heating potential of methane and nitrous oxide emissions.<sup>106</sup> These additional metrics used the same economic models, the same treatment of uncertainty, and the same methodological assumptions that IWG applied to the social cost of carbon, and these new estimates underwent rigorous peer-review.<sup>107</sup>

IWG’s methodology has been repeatedly endorsed by reviewers. In 2014, the U.S. Government Accountability Office concluded that IWG had followed a “consensus-based” approach, relied on peer-reviewed academic literature, disclosed relevant limitations, and adequately planned to incorporate new information through public comments and updated research.<sup>108</sup> In 2016 and 2017, the National Academies of Sciences issued two reports that, while recommending future improvements to the

methodology, supported the continued use of the existing IWG estimates.<sup>109</sup> And in 2016, the U.S. Court of Appeals for the Seventh Circuit held that the Department of Energy's reliance on IWG's social cost of carbon was reasonable.<sup>110</sup> It is, therefore, unsurprising that leading economists and climate policy experts have endorsed the Working Group's values as the best available estimates.<sup>111</sup>

Furthermore, uncertainty over the values or range of values included in the IWG's social costs of greenhouse gases metric is *not* a reason to abandon the social cost of greenhouse gas methodologies;<sup>112</sup> quite the contrary, uncertainty supports higher estimates of the social cost of greenhouse gases, because most uncertainties regarding climate change entail tipping points, catastrophic risks, and unknown unknowns about the damages of climate change. Because the key uncertainties of climate change include the risk of irreversible catastrophes, applying an options value framework to the regulatory context strengthens the case for ambitious regulatory action to reduce greenhouse gas emissions. Dismissing the social cost of greenhouse gases metric because there is a range of potential estimates has been rejected by the Ninth Circuit in *Center for Biological Diversity*—“while . . . there is a range of values, the value of carbon emissions reduction is certainly not zero”<sup>113</sup>—but the range of values recommended by the Interagency Working Group<sup>114</sup> and endorsed by the National Academies of Sciences<sup>115</sup> is rather manageable. In 2016, the IWG recommended values at discount rates from 2.5% to 5%, calculated as between \$12 and \$62 for year 2020 emissions.<sup>116</sup> Numerous federal agencies have had no difficulty either applying this range in their environmental impact statements or else focusing on the central estimate at a 3% discount rate.<sup>117</sup> Most recently, in August 2017, the Bureau of Ocean Energy Management applied the IWG's range of estimates calculated at three discount rates (2.5%, 3%, and 5%) to its environmental impact statement for an offshore oil development plan,<sup>118</sup> and called this range of estimates “a useful measure to assess the benefits of CO<sub>2</sub> reductions and inform agency decisions.”<sup>119</sup>

### **A Recent Executive Order Does Not Change the Requirements to Monetize Climate Damages**

In March 2017, President Trump disbanded the IWG and withdrew their technical support documents.<sup>120</sup> Nevertheless, Executive Order 13,783 assumes that federal agencies will continue to “monetiz[e] the value of changes in greenhouse gas emissions” and instructs agencies to ensure such estimates are “consistent with the guidance contained in OMB Circular A-4.”<sup>121</sup> Consequently, while federal agencies no longer benefit from ongoing technical support from the IWG on use of the social cost of greenhouse gases, by no means does the new Executive Order imply that agencies should not monetize important effects in their environmental impact statements. The Executive Order does not prohibit agencies from relying on the same choice of models as the IWG, the same inputs and assumptions as the IWG, the same statistical methodologies as the IWG, or the same ultimate values as derived by the IWG. To the contrary, because the Executive Order requires consistency with Circular A-4, as agencies follow the Circular’s standards for using the best available data and methodologies, they will necessarily choose similar data, methodologies, and estimates as the IWG, since the IWG’s work continues to represent the best available estimates.<sup>122</sup> The Executive Order does not preclude agencies from using the same range of estimates as developed by the IWG, so long as the agency explains that the data and methodology that produced those estimates are consistent with Circular A-4 and, more broadly, with standards for rational decisionmaking.

Similarly, the Executive Order’s withdrawal of the Council on Environmental Quality’s guidance on greenhouse gases,<sup>123</sup> does not—and legally cannot—remove agencies’ statutory requirement to fully disclose the environmental impacts of greenhouse gas emissions. As the Council on Environmental Quality explained in its withdrawal, the “guidance was not a regulation,” and “[t]he withdrawal of the guidance does not change any law, regulation, or other legally binding requirement.”<sup>124</sup> In other words, when the guidance originally recommended the appropriate use of the social cost of greenhouse gases in environmental impact statements,<sup>125</sup> it was simply explaining that the social cost of greenhouse gases is consistent with longstanding NEPA regulations and case law, all of which are still in effect today.

Notably, some agencies under the Trump administration have continued to use the IWG estimates even following the Executive Order. For example, in August 2017, the Bureau of Ocean Energy Management called the social cost of carbon “a useful measure” and applied it to analyze the consequences of offshore oil and gas drilling.<sup>126</sup> And in July 2017, the Department of Energy used the IWG’s estimates for carbon and methane emissions to analyze energy efficiency regulation, describing the social cost of methane as having “undergone multiple stages of peer review.”<sup>127</sup>

Two agencies have developed new “interim” values of the social cost of greenhouse gases following the Executive Order. Relying on faulty economic theory, these “interim” estimates drop the social cost of carbon from \$50 per ton in year 2020 down to as little as \$1 per ton, and drop the social cost of methane from \$1420 per ton in year 2020 down to \$58. These “interim” estimates are inconsistent with accepted science and economics; the IWG’s 2016 estimates remain the best available estimates. The IWG’s methodology and estimates have been repeatedly endorsed by reviewers as transparent, consensus-based, and firmly grounded in the academic literature. By contrast, the “interim” estimates ignore the interconnected, global nature of our climate-vulnerable economy, and obscure the devastating effects that climate change will have on younger and future generations. BLM should not use the “interim” social cost of greenhouse gas estimates because of their methodological flaws, as described more fully in the attached comments which we have previously submitted to BLM on its misleading use of the unsupported “interim” values.
