To: Environmental Protection Agency

Submitted By: Center for Climate and Energy Solutions, Clean Air Task Force, Environmental Defense Fund, Institute for Policy Integrity at New York University School of Law, Montana Environmental Information Center, Natural Resources Defense Council, Sierra Club, Union of Concerned Scientists

Subject: Comments on the Consideration of the Social Cost of Greenhouse Gases in Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43,726 (Aug. 10, 2021) (Docket No. EPA-HQ-OAR-2021-0208)

The undersigned organizations respectfully submit the following comments¹ on the Environmental Protection Agency's application of the social cost of greenhouse gases in its proposed regulation, Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards ("Proposed Rule"),² and the draft Regulatory Impact Analysis accompanying that proposal ("RIA").³

EPA appropriately applies the social cost estimates developed by the Interagency Working Group on the Social Cost of Greenhouse Gases ("Working Group") and rejects the faulty numbers that EPA applied from 2017 until early 2021. The Working Group developed its social cost estimates through a rigorous and transparent process incorporating the best available science. Those values—though widely agreed to underestimate the full social costs of greenhouse gas emissions⁴—are appropriate to use as conservative estimates and have been

¹ Our organizations may separately and independently submit other comments to this docket. This document does not purport to represent the views, if any, of New York University School of Law.

² 86 Fed. Reg. 43,726 (Aug. 10, 2021).

³ EPA, Regulatory Impact Analysis: Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (Aug. 2021) ("RIA").

⁴ Interagency Working Group on the Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide – Interim Estimates Under Executive Order 13,990 at 4 (2021) [hereinafter "2021 TSD"] (acknowledging that current social cost valuations "likely underestimate societal damages from [greenhouse gas] emissions"). Richard L. Revesz et al., *Global Warming: Improve Economic Models of Climate Change*, 508 NATURE 173 (2014) (explaining that the Working Group's values, though methodically rigorous and highly useful, are very likely underestimates) (note that co-author Kenneth Arrow is a Nobel Prize-winning economist).

applied in dozens of previous rulemakings⁵ and upheld in federal court.⁶ In contrast, the estimates that EPA and other federal agencies applied during the Trump administration disregarded the best available science and were rejected by a federal court as arbitrary and capricious.⁷

EPA provides several compelling justifications for readopting the Working Group’s estimates. But while the legal challenges that have already been brought against the Working Group’s estimates are unfounded,⁸ EPA should anticipate similar legal challenges to its application of the social cost of greenhouse gases and so provide additional justifications for its policy choices on this consequential issue.⁹ In particular, **EPA should expand upon its justifications for adopting a global damages valuation and for the range of discount rates it applies to climate effects.** As detailed herein, there are many additional legal, economic, and policy justifications for such methodological decisions that can further bolster EPA’s support for these choices. EPA should also strongly consider conducting supplemental sensitivity analyses to further confirm that strengthening the vehicle emissions standards will deliver significant net benefits to society under a range of analytical assumptions.

These comments are organized into five sections. First, as Section I recommends, EPA should both **explicitly affirm that, in EPA’s own expert judgment, those estimates are appropriate but conservative lower bounds that omit significant categories of climate damages.**

Section II recommends that EPA provide additional justification for adopting a global framework for valuing climate impacts. These include legal justifications based on the Clean Air Act, the National Environmental Policy Act’s broad government-wide policy mandates, the Administrative Procedure Act’s requirement to consider all important factors, and executive orders and international agreements. EPA can similarly strengthen its economic and policy justifications, such as by **explicitly concluding that the theory and evidence for international reciprocity justify a focus on the full global values.** Section II also recommends that EPA modify its discussion of domestic-only estimates. The RIA currently uses, in a footnote, the flawed domestic-only values developed under the now-revoked Executive Order 13,783.¹⁰ Though EPA correctly judges those values to be underestimates, they are actually fatally

Aug. 31, 2021) (dismissing lawsuit brought against the Working Group’s valuations); Iliana Paul & Max Sarinsky, Inst. for Pol’y Integrity, *Playing With Fire: Responding to Criticism of the Social Cost of Greenhouse Gases* (2021), <https://policyintegrity.org/publications/detail/playing-with-fire> (rebutting substantive arguments presented in that case and another lawsuit brought by the State of Louisiana).

⁹ See *Encino Motorcars, LLC v. Navarro*, 136 S. Ct. 2117, 2126 (2016) (explaining that when an agency changes its position on an issue, it must “at least ‘display awareness that it is changing position’ and ‘show that there are good reasons for the new policy’” (quoting *FCC v. Fox Television Stations Inc.*, 556 U.S. 502, 515 (2009))).

¹⁰ RIA at 3-36 note n.

incomplete¹¹ and should not be used. EPA should instead consider conducting sensitivity analysis using a sounder domestic-only estimate as a backstop to minimize legal risk.

Section III recommends that EPA provide additional justification for adopting the range of discount rates endorsed by the Working Group and for appropriately deciding not to apply a 7% capital-based discount rate to climate impacts. In particular, **EPA should provide additional justification for combining climate effects discounted at an appropriate consumption-based rate with other costs and benefits discounted at a capital-based rate.** Besides climate effects presenting special legal, economic, and policy considerations for the discount rate, EPA should also argue that it is appropriate generally to focus its analysis of this rule on consumption-based rates given that most costs and benefits are projected to fall to consumption rather than to capital investments. We also urge EPA to consider providing additional sensitivity analysis using discount rates of 2% or lower for climate impacts, as recently suggested by the Working Group.

Section IV recommends that EPA bolster its justification for relying on the Working Group's other methodological choices, including the fact that the Working Group applied a transparent and rigorous process that relied upon the best-available and most widely-cited models for monetizing climate damages. This section also provides detailed **rebuttals to common criticisms of the Working Group's methodology** from opponents of climate regulation.

Finally, Section V encourages EPA to apply the social cost of greenhouse gases estimates that it developed through 2070, to coordinate with the Working Group (of which EPA is a member) to adopt social cost values through at least that time period, and more broadly to **extend its analytical time frame to capture all significant benefits.**

I. EPA Should Affirm That, in Its Expert Judgment, the Working Group's Social Cost of Greenhouse Gas Estimates Are Appropriate But Conservative

Both the Proposed Rule¹² and the RIA¹³ cite and quote the Working Group's February 2021 Technical Support Document as support for the methodological choices underlying the social cost of greenhouse gas values that EPA applies in its analysis. In particular, EPA cites the Working Group's conclusion that the values "likely underestimate" climate damages.¹⁴ Such references provide compelling justifications for applying the Working Group's estimates as appropriate lower bounds. However, EPA should take the additional steps of explicitly incorporating the Working Group's entire Technical Support Document by reference, and then affirming that in EPA's own judgment, the values it endorses are conservative underestimates.

These additional steps will serve two important goals. First, they will help shield EPA from any attacks that the agency's reliance on the Working Group's guidance or its justification for the values is in any way incomplete. Second, they will bolster the case that stronger vehicle emission standards will deliver significant net benefits to society. Notably, the Working Group's estimates do not currently reflect (due to data limitations) climate damages from many

¹¹ *Bernhardt*, 472 F. Supp. 3d at 613 (recognizing that the Trump-era estimates of domestic climate damages "ignores impacts on 8 million United States citizens living abroad, including thousands of United States military personnel; billions of dollars of physical assets owned by United States companies abroad; United States companies impacted by their trading partners and suppliers abroad; and global migration and geopolitical security").

¹² 86 Fed. Reg. at 43,789.

¹³ RIA at 3-29 to 3-35.

¹⁴ *Id.* at 3-35; 86 Fed. Reg. at 43,789 (both citing 2021 TSD, *supra* note 4, at 4.

significant effects that EPA has a statutory responsibility to consider, including ocean acidification, wildfires, public health effects from methane emissions, abrupt ecosystem disruptions, and many potentially catastrophic outcomes, to name just some categories of omitted damages.¹⁵ Because of such omitted damages and other limitations of the current estimates, the Working Group's central estimates of global damages calculated at a 3% discount rate are most likely severe underestimates of the full climate effects from greenhouse gas emissions. EPA should note in all its presentations of net benefits that its estimates of climate benefits are conservative underestimates that do not currently include many significant categories of climate damages.¹⁶

II. EPA Should Provide Additional Justification for Its Reliance on Global Climate Damage Valuations, While Considering Additional Analysis of Domestic Effects

In the Proposed Rule, EPA appropriately focuses on a global estimate of climate benefits, returning to its historical approach and correcting its recent, temporary, and arbitrary practice of disregarding all climate effects that occur outside the physical borders of the United States. While EPA offers persuasive justifications for this decision,¹⁷ it should provide additional analysis on this front.¹⁸ In particular, EPA should emphasize the concern for the impacts of U.S. pollution on foreign welfare in the Clean Air Act and other sources of law, further highlight the significance of U.S. strategic interests and reciprocity, discuss the importance of extraterritorial impacts and spillovers, and highlight the inconsistency that would occur if the agency considered only domestic benefits while focusing on global costs. At the same time, since reliance solely on a global valuation carries some legal risk, EPA may wish to conduct additional sensitivity analysis around a domestic-only valuation.

A. Relevant Statutes and Executive Orders Compel, And Certainly Permit, a Global Perspective on Climate Damages

The Clean Air Act, National Environmental Policy Act, Administrative Procedure Act, and other key sources of law not only permit, but in fact require EPA to consider international effects. EPA should highlight these legal requirements as justification for its focus on global climate impacts.

Section 202 of the Clean Air Act, under which EPA issues the Proposed Rule, charges EPA with regulating “air pollutant[s] which may be reasonably anticipated to endanger public health or welfare,”¹⁹ where “welfare” is defined to include “effects on . . . weather . . . and climate.”²⁰ When interpreting Section 202, the Supreme Court found “there is nothing

¹⁵ Climate Impacts Reflected in the SCC Estimates, COST OF CARBON, <https://costofcarbon.org/scc-climate-impacts> (listing included and omitted damages in Working Group's estimates).

¹⁶ See, e.g., 86 Fed. Reg. at 43,735 tbl. 4 (explaining, in note e, that non-greenhouse gas benefits “do not include the full complement of health and environmental effects,” but failing to mention in note b that climate benefits are similarly incomplete underestimates).

¹⁸ See generally Jason A. Schwartz, Inst. for Pol'y Integrity, *Strategically Estimating Climate Pollution Costs in a Global Environment* (2021), https://policyintegrity.org/files/publications/Strategically_Estimating_Climate_Pollution_Costs_in_a_Global_Environment.pdf.

¹⁹ 42 U.S.C. § 7521(a)(1).

²⁰ 42 U.S.C. § 7602(h); *Massachusetts v. EPA*, 127 S. Ct. 1438, 1447 (2007).

counterintuitive to the notion that EPA can curtail the emission of substances that are putting the *global* climate out of kilter.”²¹ And when industry challenged another EPA climate program by arguing that the Clean Air Act “was concerned about local, not global effects,” the U.S. Court of Appeals for the D.C. Circuit had “little trouble disposing of Industry Petitioners’ argument that the [Clean Air Act’s prevention of significant deterioration] program is specifically focused solely on localized air pollution,” finding instead that the statute was “meant to address a much broader range of harms,” including “precisely the types of harms caused by greenhouse gases.”²²

Environmental and administrative law scholar Richard Revesz, who also directs the undersigned Institute for Policy Integrity, has exhaustively reviewed the legislative history of the Clean Air Act’s definition of “welfare” and has concluded that “when Congress included the ‘effects on . . . climate’ language in the statute, it understood that adverse climate effects could occur on a global scale.”²³ For instance, Senator Caleb Boggs, a Republican from Delaware and ranking minority member of the Public Works Subcommittee on Air and Water Pollution, which was considering the Clean Air Act in 1970, entered a report into the record stating that air pollution “alters climate and may produce global changes in temperature.”²⁴ Senator Jennings Randolph of West Virginia likewise submitted a statement into the record explaining that U.S. air pollution could “produce unacceptable worldwide climate changes.”²⁵ Congress’s clear concern for the effects of domestic pollution on the global climate—many more examples of which are discussed in Professor Revesz’s article—demonstrates that a global perspective is appropriate, if not required, when EPA regulates under the Clean Air Act.

This interpretation is further compelled by the National Environmental Policy Act (“NEPA”). Though best known for requiring agencies to prepare environmental impact statements before taking certain actions (a requirement that does not apply to Clean Air Act actions),²⁶ NEPA also much more broadly declares a national environmental policy and requires of all agencies that “to the fullest extent possible[,] the policies, regulations, and public laws of the United States *shall be interpreted and administered* in accordance with the policies set forth in this chapter,”²⁷ including the need to “recognize the worldwide and long-range character of environmental problems” and to “lend appropriate support” to help “maximize international cooperation.”²⁸ In other words, especially because adopting a global perspective on climate

²⁶ While actions taken under the Clean Air Act “shall [not] be deemed a major Federal action significantly affecting the quality of the human environment within the meaning of [42 U.S.C. § 4332(2)(C)],” 15 U.S.C. § 793(c)(1), the other provisions of NEPA—including those quoted and cited in this paragraph—continue to apply.

²⁷ 42 U.S.C. § 4332(1) (emphasis added).

²⁸ *Id.* § 4332(2)(F); *see also EDF v. Massey*, 986 F.2d 528, 536 (D.C. Cir. 1993) (“Section 102(2)(F) further supports the conclusion that Congress, when enacting NEPA, was concerned with worldwide as well as domestic problems facing the environment. . . . Compliance with one of the subsections can hardly be construed to relieve the agency from its duty to fulfill the obligations articulated in other subsections.”); *NRDC v. NRC*, 647 F.2d 1345, 1387 (D.C. Cir. 1981) (J. Robinson, concurring; J. Wilkey wrote for the Court, but there was no majority opinion) (concluding that even if a conflict with another statute prevents the agency from conducting an environmental impact statement, that “does not imply that NRC may ignore its other NEPA obligations,” including the “provision

damages will advance U.S. foreign policy goals (see the next subsection), NEPA requires EPA to interpret all of its laws, including the Clean Air Act, in ways that recognize the worldwide character of environmental problems. Using global social cost of greenhouse gas estimates helps fulfill that requirement.

Other key legal commitments compel this same conclusion. For instance, the United Nations Framework Convention on Climate Change—to which the United States is a party²⁹—declares that national “policies and measures to deal with climate change should be cost-effective so as to *ensure global benefits* at the lowest possible cost.”³⁰ The Convention further commits parties to evaluating global climate effects in their policy decisions, by “employ[ing] appropriate methods, for example *impact assessments* . . . with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects or measures undertaken by them to mitigate or adapt to climate change.”³¹ The unmistakable implication of the Convention is that parties—including the United States—must account for global economic, public health, and environmental effects in their impact assessments. In 2008, a group of U.S. senators—including then-Senator John Kerry, who helped ratify the framework convention on climate change—agreed with this interpretation of the treaty language, saying that “[u]pon signing this treaty, the United States committed itself to considering the global impacts of its greenhouse gas emissions.”³²

And under the Administrative Procedure Act, it is arbitrary and capricious for agencies to “entirely fail[] to consider an important aspect of the problem”³³—an obligation that a federal court held requires federal agencies to consider international climate impacts. Specifically, a recent ruling from the U.S. Court for the Northern District of California struck down as arbitrary the Bureau of Land Management’s (“BLM”) rescission of the Waste Prevention Rule in part because the agency had abandoned the Working Group’s peer-reviewed, global estimates of the social cost of greenhouse gases in favor of flawed estimates (the same estimates that EPA applied under the Trump administration) that looked only at effects within the U.S. borders.³⁴

for multinational cooperation” and the “policy of the United States with respect to the ecological well-being of this planet”; rather, the agency “should remain cognizant of this responsibility”); *Greene County Planning Bd. v. Federal Power Comm’n*, 455 F.2d 412, 424 (2d Cir. 1972) (“The Commission’s ‘hands-off’ attitude is even more startling in view of the explicit requirement in NEPA that the Commission ‘recognize the worldwide and long-range character of environmental problems’ and interpret its mandate under the Federal Power Act in accordance with the policies set forth in NEPA.”).

³⁴ *Bernhardt*, 472 F. Supp. 3d at 613.

The court found that the global values developed by the Working Group reflected “the best available science about monetizing the impacts of greenhouse gas emissions,”³⁵ whereas “focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science.”³⁶ The court reminded BLM that relevant executive orders, including Executive Order 12,866, require consideration of “all” costs and benefits, based on the “best reasonably obtainable scientific, technical, economic, and other information,” and concluded that “no[] . . . regulatory rules or orders require exclusion of global impacts.”³⁷ More recently, Executive Order 13,990 instructed agencies to “tak[e] global damages into account,” because “[d]oing so facilitates sound decision-making, recognizes the breadth of climate impacts, and support the international leadership of the United States on climate issues.”³⁸ This language again reinforces the instructions from NEPA that, whenever not precluded by statute from doing so, agencies should account for the environmental impacts of their actions on foreign nations.

EPA should draw upon these legal authorities in justifying its reliance on global climate-damage valuations.

B. Focusing on Global Climate Damages Furthers U.S. Strategic Interests by Facilitating Reciprocity, Mitigating International Spillover Effects, and Protecting U.S. Extraterritorial Interests

EPA explains that the Working Group selected a global perspective because climate impacts occurring outside U.S. borders can directly and indirectly affect U.S. welfare through spillovers and foreign reciprocity, and that EPA is readopting that global perspective consistent with its approach from 2009–2016.³⁹ EPA should expand on this justification. In particular, EPA should explicitly explain why the theory and evidence for reciprocity by itself justifies a focus on the full global values, and that additional strategic and practical justifications provide further support.

1. Use of the Global Values Facilitates International Reciprocity

Because the world’s climate is a single interconnected system, the United States benefits greatly when foreign countries consider the global externalities of their greenhouse gas pollution and cut emissions accordingly. It therefore promotes the strategic interests of the United States to encourage all other countries to think globally in setting their climate policies. The United States can advance this objective by itself adopting the full global social cost of greenhouse gases—as numerous leading climate economists and experts have explained.⁴⁰ Indeed, basic economic

³⁵ *Id.* at 611.

³⁷ *Id.* at 611–12 (internal quotation marks omitted).

³⁸ Exec. Order No. 13,990 § 5(a), 86 Fed. Reg. 7037, 7040 (Jan. 20, 2021).

³⁹ RIA at 3-29.

⁴⁰ Most generally, it is individually rational for a country to fully internalize the global social cost of greenhouse gases “if a country expects a decrease in its own emissions to decrease that of all others in proportion to the ratio of its external cost of emissions to its internal costs.” Matthew J. Kotchen, *Which Social Cost of Carbon? A Theoretical Perspective*, 5 J. ASSOC. ENV’T. & RES. ECON. 673, 683 (2017). Other economists have justified use of the global social cost estimates on more intuitive grounds. *See, e.g.*, Tamma Carleton & Michael Greenstone, *Updating the United States Government’s Social Cost of Carbon* at 26-27 (Becker Friedman Institute Working Paper 2021-04, Jan. 2021), <https://perma.cc/H9EU-XWBX> (“The global SCC . . . is an ingredient in efforts to procure the necessary international action. . . . Even if policymakers decide that the effects of regulations on U.S. citizens are what matter (in terms of both law and policy), it would make sense to use the global measure, as it would protect U.S. citizens

principles demonstrate that the United States stands to benefit greatly if all countries apply global social cost of greenhouse gas values in their regulatory decisions and project reviews⁴¹—likely trillions of dollars in direct benefits from foreign action to combat climate change.⁴²

The Biden Administration has clearly made such a strategic choice, to adopt a global valuation of climate damages as part of its diplomatic strategy. Executive Order 13,990 unequivocally states that “[i]t is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account . . . [to] support the international leadership of the United States on climate issues.”⁴³ The Order later elaborates: “Our domestic efforts must go hand in hand with U.S. diplomatic engagement. Because most greenhouse gas emissions originate beyond our borders, such engagement is more necessary and urgent than ever. The United States must be in a position to exercise vigorous climate leadership in order to achieve a significant increase in global climate action and put the world on a sustainable climate pathway.”⁴⁴

There is already evidence that the U.S. strategy of combining its domestic efforts—including the global valuation of climate damages—with its diplomatic engagement is spurring foreign reciprocity. During the April 2021 “Leaders’ Summit on Climate” hosted by the United States, following the announcement of a new U.S. commitment to reduce emissions to 50–52% below 2005 levels by 2030, multiple other countries reciprocally increased the ambition of their own climate targets. Notably, Japan accelerated its reduction goal from 26% to 46–50%; Canada strengthened its target from 30% to 40–45%; the European Union set a target of at least 55%; the United Kingdom set a new target for the year 2035; South Korea strengthened its target to achieve net zero emissions by 2050; China promised to peak coal use by 2025 and phase down coal consumption after that, and to join the Kigali Amendment to reduce hydrofluorocarbon emissions; Argentina pledged to strengthen its goal by 2.7% and make previously “conditional” targets “unconditional” instead; Brazil committed to a net zero target by 2050 (ten years earlier than its previous 2060 goal) and pledged to end illegal deforestation by 2030; South Africa shifted its emission peak ten years earlier, to 2025; and New Zealand, Bhutan, and Bangladesh all committed to submit more ambitious plans in the near future.⁴⁵

against a range of adverse effects from unmitigated climate change.”); William Pizer et al., *Using and Improving the Social Cost of Carbon*, 346 *SCIENCE* 1189, 1190 (2014) (explaining that the “potential to leverage foreign mitigation,” combined with moral, ethical, and security issues, provide “compelling reasons to focus on a global SCC but, more important, to make a strategic choice.”); Robert S. Pindyck, Comments on Proposed Rule and Regulatory Impact Analysis on the Delay and Suspension of Certain Requirements for Waste Prevention and Resource Conservation, Nov. 6, 2017, *available at* <https://perma.cc/HG8Q-MT6H> (“[W]hat treatment of international damages is in the United States’ self-interest? . . . The simplest answer is to find the value of the [social cost of carbon] that maximizes global welfare. . . . I continue to think that the global value is the appropriate provisional value for use as research on this topic continues.”).

⁴¹ See Kotchen, *supra* note 40, at 678 (providing formulas for the “efficiency argument in support of all countries internalizing the GSCC [global social cost of carbon] for domestic policy”).

⁴² Inst. for Pol’y Integrity, *Foreign Action, Domestic Windfall: The U.S. Economy Stands to Gain Trillions from Foreign Climate Action* (2015), <https://perma.cc/T3WN-H42U>.

⁴³ Exec. Order No 13,990 § 5(a).

⁴⁴ *Id.* § 6(d). Though this subsection takes action on the Keystone XL Pipeline permit, its statement of diplomatic goals has much broader relevance.

⁴⁵ U.S. Dept. of State, Leaders’ Summit on Climate: Day 1, Apr. 22, 2021, <https://perma.cc/3X8A-KF4G>; Climate Action Tracker, *Warming Projections Global Update: May 2021* at 3 (2021), <https://perma.cc/7JYN-N2DU>.

This flurry of activity is just the latest evidence of reciprocity in international climate actions. Some past reciprocity has been explicit. The Kigali Amendment, for example, is the latest internationally negotiated climate treaty, with more than 120 parties so far committing to common but differentiated responsibilities to phase down hydrofluorocarbons.⁴⁶ Previously, under the Copenhagen Accord and the Paris Agreement, some parties, including the European Union and Mexico, have at times explicitly made conditional pledges, promising to ratchet up their efforts if other countries make comparable reductions.⁴⁷ By contrast, when the United States “failed to take action to reduce greenhouse gas emissions during the George W. Bush Administration and during . . . the Trump Administration,” as economist Michael Greenstone has testified before the U.S. House of Representatives, “both periods were characterized by little [international] progress, and indeed many instances of backsliding, in reducing emissions globally.”⁴⁸ By failing to take international climate damages into account, in other words, EPA and other U.S. agencies would incentivize other countries to do the same, which in turn would cause greater greenhouse gas pollution originating in other countries that causes climate damage within the United States.

In January 2021, Trevor Houser and Kate Larsen published a conservative estimate of the number of tons of greenhouse gases that the rest of the world has committed to reduce for each ton that the United States has pledged to reduce: a figure they call the “Climate Reciprocity Ratio.”⁴⁹ Using only the quantifiable, unconditional pledges that 51 countries have made since 2014 to cut emissions through 2030, Houser and Larsen conservatively estimate that for every ton the United States pledged to reduce, these other countries have pledged 6.1–6.8 tons in return.⁵⁰ While implementation of all these foreign policies is not guaranteed, Houser and Larsen cite evidence that several large emitters are on track to meet their goals, and that the ratio should grow over time as the U.S. share of global emissions falls.⁵¹

In short, both empirical evidence and economic theory strongly support a strategic choice for U.S. agencies to adopt the full global estimates of the social cost of greenhouse gases, as this

⁴⁶ See U.N., Kigali Amendment to the Montreal Protocol on Substances that Deplete the Ozone Layer (2016), <https://perma.cc/SEX3-HAQA> (last visited June 8, 2021).

⁴⁷ See Eur. Comm’n, Expression of Willingness to Be Associated with the Copenhagen Accord and Submission of the Quantified Economy-Wide Emissions Reduction Targets for 2020 at 2, Jan. 28, 2010, <https://perma.cc/77DD-M4LS> (committing to a 20% reduction but “reiterat[ing] its conditional offer to move to a 30% reduction by 2020 compared to 1990 levels, provided that other developed countries commit themselves to comparable emission reductions and that developing countries contribute adequately according to their responsibilities and respective capabilities”); Gov’t of Mex. Ministry of Env’t. and Nat. Res., Nationally Determined Contributions: 2020 Update at 22, <https://perma.cc/VF4A-K5HK> (making an unconditional pledge of 22% reduction of GHGs and 51% of black carbon by 2030; and making a conditional pledge of up to 36% reduction GHGs and 70% black carbon, conditioned on “an international price for carbon trading, adjustment of tariffs for carbon content” as well as technology transfers and financial resources).

⁴⁸ Economics of Climate Change: Hearing before the U.S. H. Comm. on Oversight & Reform’s Subcomm. on Env’t at 6 (Dec. 19, 2019) (testimony of Michael Greenstone), *available at* <https://perma.cc/H5JS-V4H6>.

⁴⁹ Trevor Houser & Kate Larsen, *Calculating the Climate Reciprocity Ratio for the U.S.*, Rhodium Group, Jan. 21, 2021 (calling their estimate “deliberately conservative”).

⁵⁰ The estimate is conservative because it omits any conditional pledges, any pledges that are not readily quantified into specific reductions, any actions from countries that have not formally submitted Nationally Determined Contributions to the United Nations, any reductions occurring after 2030, and any foreign actions already achieved before 2014 that may have motivated U.S. pledges in the first place. *Id.*

⁵¹ *Id.*

facilitates international reductions in greenhouse gas pollution that directly benefits the United States. EPA should therefore explicitly make the case that current evidence of foreign reciprocity supports a focus on the full global valuations of the social cost of greenhouse gases.

2. Use of the Global Values Recognizes Spillover Impacts from Climate Change

Significant costs to trade, human health, and security will inevitably “spill over” to the United States as other regions of the planet experience climate change damages.⁵² Due to its unique place among countries—both as the largest economy with trade- and investment-dependent links throughout the world, and as a military superpower—the United States is particularly vulnerable to effects that will spill over from other regions of the world. Use of global damage values recognizes these spillover effects, which were ignored under the Trump administration’s domestic-only valuation.

These spillover effects take many forms. In terms of trade-related impacts, for one, as climate change disrupts the economies of other countries, decreased availability of imported inputs, intermediary goods, and consumption goods will cause supply shocks to the U.S. economy, causing particularly damaging disruptions in sectors such as agriculture and technology. Similarly, the U.S. economy will experience demand shocks as climate-affected countries decrease their demand for U.S. goods. U.S. trade and businesses that rely on foreign-owned infrastructure, services, and resources will suffer.⁵³ Financial markets will also suffer as foreign countries become less able to loan money to the United States and as the value of U.S. firms declines with shrinking foreign profits. As seen historically, economic disruptions in one country can cause financial crises that reverberate globally at a breakneck pace.⁵⁴

Climate change is also predicted to exacerbate existing security threats—and possibly catalyze new security threats—to the United States.⁵⁵ Besides threats to U.S. military installations and operations at home and abroad from flooding, storms, extreme heat, and wildfires,⁵⁶ climate change is also a “source[] of conflict around the world”⁵⁷ and a “threat multiplier” that, as recognized by the Department of Defense, will “aggravate stressors abroad such as poverty, environmental degradation, political instability, and social tensions—conditions that can enable terrorist activity and other forms of violence.”⁵⁸ Climate change will create and

⁵² Though some positive spillover effects are also possible, such as technology spillovers that reduce the cost of mitigation or adaptation, see S. Rao et al., *Importance of Technological Change and Spillovers in Long-Term Climate Policy*, 27 ENERGY J. 123–39 (2006), overall climate spillovers are likely strongly negative, see Jody Freeman & Andrew Guzman, *Climate Change and U.S. Interests*, 109 COLUM. L. REV. 1531 (2009).

⁵³ U.S. Global Change Res. Prog., Fourth National Climate Assessment, Volume II: Impacts, Risks, and Adaptation in the United States, Chapter 16: Climate Effects on U.S. International Interests 608 (2018) [hereinafter “NCA4”].

⁵⁴ See Steven L. Schwarcz, *Systemic Risk*, 97 GEO. L.J. 193, 249 (2008) (observing that financial collapse in one country is inevitably felt beyond that country’s borders).

⁵⁸ U.S. Dep’t of Def., *Quadrennial Defense Review 2014* at vi, 8 (2014).

exacerbate new conflicts and humanitarian crises that will require a U.S. response, even as climate change also complicates the logistics of deploying forces and achieving missions.

Climate change will also very directly cause spillover damages across transboundary resources. The United States has already begun to experience increased smoke from Canadian wildfires and drought conditions that spread along the U.S.-Mexico border.⁵⁹ The United States shares a maritime border with 21 other countries, shares water resources like the Columbia River with our neighbors, and shares ecosystems—including the oceans through which migratory species with high economic and ecosystem-service values, like the Pacific hake, travel and live.⁶⁰

All of these individual spillover effects can also interact and trigger feedback loops that will propagate additional spillover damages.⁶¹ Economic shocks around the world can make it more difficult for other countries to continue investing in mitigation and abatement, thus hastening the pace of climate change.⁶² Conflict and political instability caused by climate change can further reduce the willingness or ability of countries to engage in domestic climate policy or international cooperation.⁶³ Spillover effects can chain together: if climate change accelerates migration, the attendant economic ripple effects and spread of health risks may cause political instability, which in turn can cause more migration and further economic ripple effects, thus starting the feedback loop again.⁶⁴

Some experts on the social cost of greenhouse gases have therefore concluded that, because the integrated assessment models that underlie the Working Group’s social cost valuations currently do not capture many of these key inter-regional costs, use of the global values can be further justified as a proxy for capturing all spillover effects.⁶⁵ Though not all

Howard & Livermore, *supra* note 61.

⁶⁵ Robert E. Kopp & Bryan K. Mignone, *Circumspection, Reciprocity, and Optimal Carbon Prices*, 120 CLIMATE CHANGE 831, 833 (2013) (2013) (explaining that the principle of “circumspection” can account for spillover effects and can then be used to justify a global SCC value).

Notably, in Katharine Ricke et al., *Country-Level Social Cost of Carbon*, 8 NATURE CLIMATE CHANGE 895 (2018), the authors concede that after factoring in spillovers and other considerations, an individual country’s interests may be better reflected in a global valuation than a country-specific valuation, and it may not be appropriate to use a country-specific valuation in setting climate policies:

Globalization and the many avenues by which the fortunes of countries are linked mean that a high CSCC in one place may result in costs as the global climate changes even in places where the CSCC is nominally negative. For many countries, the effects of climate change may be felt more greatly through transboundary effects, such as trade disruptions, large-scale migration, or liability exposure than through local climate damage. . . . These considerations suggest that country-level interests may be *more closely aligned to global interests than indicated by contemporary country-level contributions* to the SCC. . . . [A] host of other *strategic and ethical considerations* factor into the international relations of climate change mitigation. . . . We make no claim here regarding the utility of the CSCC in setting climate policies. CO₂ emissions are a global externality.

climate damages will spill back to affect the United States, many will, and together with other justifications, the likelihood of significant spillovers makes a global valuation the better, more transparent accounting of the full range of costs and benefits that matter to U.S. policymakers and the public. EPA can therefore highlight spillover impacts as further justification for relying on global social cost valuations. In addition to the spillover effects that EPA already mentions,⁶⁶ EPA should argue that transboundary spillovers, feedback loops, information spillovers, and other effects justify a focus on the full global values, either independently or in combination with other strategic and ethical considerations.⁶⁷

3. *Use of the Global Values Preserves Extraterritorial Interests*

The RIA mentions direct and indirect impacts to U.S. citizens and assets located abroad as a justification for a global valuation,⁶⁸ but U.S. extraterritorial interests are even more extensive and significant. A domestic-only estimate of the social cost of greenhouse gases based on some rigid conception of geographic borders or U.S. share of world GDP will fail to capture all the climate-related costs and benefits that matter to U.S. citizens, including impacts to significant U.S. ownership interests in foreign businesses, properties, and other assets, as well as U.S. consumption abroad including tourism,⁶⁹ and even effects to the millions of Americans living abroad.⁷⁰ The United States also has military personnel and assets located in almost every nation across the globe, and many if not all installations abroad—including those with high replacement costs or irreplaceable strategic value—face imminent climate risks.⁷¹ Because no methodology for estimating a “domestic-only” value would capture these impacts to extraterritorial interests, focusing on the global values can be further justified in part as a proxy for these important considerations.

The Office of Management and Budget’s *Circular A-4* guidance on conducting regulatory impact analysis requires agencies to count all significant costs and benefits, including “use” values as well as “non-use” values like bequest and existence values.⁷² *Circular A-4* cautions that “ignoring these values” may cause analyses to “significantly understate the benefits and/or costs” involved.⁷³ Similarly, *Circular A-4* recognizes that U.S. citizens may have “altruism for the health and welfare of others,” and instructs agencies that when “there is evidence of selective altruism, it needs to be considered specifically in both benefits and costs.”⁷⁴

⁷² A bequest value captures willingness to pay to preserve a resource for a future generation. Existence value captures willingness to pay to preserve a resource even with no intention to ever use or bequeath the resource. Off. of Mgmt. & Budget, *Circular A-4: Regulatory Analysis* 22 (2003).

⁷³ *Id.*

⁷⁴ *Id.*

U.S. citizens will experience costs because of their use values, non-use values, and altruistic values attached to climate effects occurring outside the U.S. borders.

Such non-use and altruistic values take many forms. For one, the United States and its citizens have a willingness to pay—as well as a legal obligation—to protect the global commons of the oceans and Antarctica from climate damages. Furthermore, a quarter of the U.S. population consists of either foreign-born immigrants or second-generation residents,⁷⁵ and subsequent generations of Americans retain significant familial, cultural, economic, and religious ties to their ancestors' home nations across the world.⁷⁶ U.S. citizens and residents have a significant willingness to pay to protect their relatives, ancestral homes, and cultural and religious sites located abroad.⁷⁷ Similarly, U.S. citizens value natural resources and plant and animal lives abroad—even if they never see or use those resources—and care about the health and welfare of unrelated foreign citizens⁷⁸ and cultural and world heritage sites threatened by climate change.⁷⁹ This altruism is “selective altruism,” consistent with *Circular A-4*, because the United States is directly responsible for a huge amount of the historic emissions contributing to climate change.⁸⁰

Both strategic considerations and the need to account for spillovers already provide independent justifications for focusing on the full global social cost of greenhouse gas estimates. But the global values can also be at least partly justified as a proxy for these extra-territorial interests that otherwise would be overlooked using a domestic-only damage estimate. EPA can therefore highlight U.S. extraterritorial interests as further justification for relying on global social cost valuations, and should specifically call attention to climate-vulnerable U.S. military installations abroad with high replacement costs or irreplaceable strategic value, U.S. willingness to pay to protect relatives, ancestral homes, cultural and religious sites, and natural resources

located abroad, and U.S. altruism toward the people, animals, and natural habitats across the globe.

C. Focusing on Global Climate Damages Is Consistent With EPA's Consideration of Global Costs

EPA can further justify its focus on global climate benefits as necessary for consistency with the rest of its analysis. To begin, EPA decided to treat monopsony impacts as an international transfer payment, rather than as potential benefits to U.S. consumers at the expense of foreign oil producers.⁸¹ As *Circular A-4* suggests, an analysis adopts a global rather than U.S.-centered perspective when it treats such international flows as transfers rather than as costs or benefits.⁸² And while a global perspective on climate damages can be justified on strategic grounds that would not necessarily compel also treating monopsony effects as transfers rather than as U.S. benefits, adopting a global perspective on such monopsony effects is consistent with adopting a global perspective on climate effects.

More broadly, EPA's analysis implicitly takes a global perspective on technology costs, and so it would be arbitrary not to take a global perspective on climate effects as well. All industry compliance costs ultimately fall on the owners, employees, or customers of regulated and affected firms. Whether the Proposed Rule's technology costs are passed to consumers or investors, or some combination thereof, a significant portion of the Proposed Rule's alleged compliance costs will ultimately accrue to foreign customers or foreign investors. Regulated manufacturers include major corporations that are headquartered abroad or that are publicly traded with investors across the globe.⁸³ Consumers similarly include corporate fleets of passenger vehicles and light-duty trucks owned by foreign entities or by public corporations with foreign shareholders.⁸⁴ In general, about 29% of U.S. corporate debt and 14% of equities are foreign-owned,⁸⁵ and adding foreign direct investment to portfolio stock ownership suggests that foreigners own about 40% of U.S. corporate equity.⁸⁶ Thus, a significant share of technology costs may fall on foreign entities, but EPA never distinguishes between those costs that would accrue to foreign entities as opposed to U.S. citizens or U.S. entities, and so its calculations of

⁸¹ RIA at 3-25; 86 Fed. Reg. at 43,792.

⁸² *Circular A-4* at 38 (stating that if “the analysis is conducted from the United States perspective,” then “transfers from the United States to other nations should be included as costs, and transfers from other nations to the United States as benefits”).

⁸³ Stellantis, which has been subject to the largest penalties in recent years for noncompliance, is based in the Netherlands. Volkswagen, Mercedes-Benz, and BMW are based in Germany. Mazda, Honda, Toyota, and Nissan are based in Japan. Yet in the Proposed Rule, EPA does not distinguish between compliance costs that would fall upon Japanese investors, German investors, Dutch investors, or American investors.

⁸⁴ Agrium, for example, a subsidiary of Canadian-based Nutrien, operates one of the largest corporate fleets of pickup trucks operating in the United States, 6 FleetTrax, *The Largest Fleets in America*, <https://fleettrax.net/largest-fleets-america/> (“Agrium also owns and operates a staggering 7,627 pickup trucks and cargo vans—a record number for this list.”; reporting on “the largest private fleets operating in the United States”). Large fleets are also owned by public companies like Hertz. Norway's Government Pension Fund, for example, owns 1% of Hertz. <https://www.nbim.no/en/the-fund/investments/#/2019/investments/equities/3799/Hertz%20Global%20Holdings%20Inc>.

⁸⁵ Dept. of Treasury et al., *Foreign Portfolio Holdings of U.S. Securities* at B-3 (2020), <https://perma.cc/6VP6-PPG6>.

⁸⁶ Steve Rosenthal & Theo Burke, *Who's Left to Tax? U.S. Taxation of Corporations and Their Shareholders* at 2 (Urban-Brookings Tax Policy Center Working Paper, 2020), <https://perma.cc/YMR2-XREM>.

cost implicitly include all global effects. Considering global climate benefits is consistent with that approach.

In a few recent analyses, agencies including EPA have admitted that some portion of the costs or cost savings calculated for publicly-traded corporations will “accru[e] to entities outside U.S. borders” through foreign ownership, employment, or consumption.⁸⁷ Yet much like in the Proposed Rule, these analyses do not attempt to separate out such effects to foreign interests, nor attempt to exclude such effects from consideration altogether. Indeed, splitting corporate effects into subparts based on ultimate ownership—much like separating climate benefits geographically—could be extremely complicated.⁸⁸ Thus, as a practical matter, agencies typically count all costs or benefits to corporations, no matter how those effects may be passed through to foreign owners, foreign employees, or foreign customers.

Since EPA analyzes the Proposed Rule’s costs globally—without distinguishing between U.S. and foreign effects—it would be inconsistent and arbitrary for the agency to attempt to separate out and disregard climate benefits that occur abroad, as doing so would “put a thumb on the scale” by treating costs globally but benefits domestically.⁸⁹ EPA can therefore highlight its consistent treatment of costs and benefits as further justification for relying on global social cost of greenhouse gas valuations.

D. EPA Should Replace Its References to the “Interim” Domestic-Only Values Created Under Executive Order 13,783, and Instead Consider a Different Sensitivity Analysis as a Backstop to Minimize Legal Risks

While EPA correctly relies on global social cost of greenhouse gases values to assess the Proposed Rule’s benefits, it should modify its limited discussion of the rule’s domestic climate impacts. In a footnote, EPA applies the flawed domestic-only values developed under the now-revoked Executive Order 13,783. But those numbers are fatally incomplete and thus should not be used. Instead, EPA should consider conducting sensitivity analysis using a sounder domestic-only estimate as a backstop to minimize legal risk.

To begin, EPA should delete a stray reference in its RIA to social cost of greenhouse gas values created under the now-revoked Executive Order 13,783 that could be misinterpreted. In note j on page 3-29, the RIA writes: “The values used in the SAFE rule RIA were interim values developed under E.O. 13783 for use in regulatory analyses. EPA followed E.O. 13783 by using SC-CO₂ estimates reflecting impacts occurring within U.S. borders and 3% and 7% discount rates *in our central analysis for the proposal RIA*.”⁹⁰ Though likely intended to refer only to the values EPA used in the proposed and final RIA for the SAFE Rule, the wording of the final phrase is ambiguous and could be misinterpreted as suggesting EPA is continuing to use such

⁸⁷ See, e.g., EPA, Regulatory Impact Analysis for the Proposed Reconsideration of the Oil and Natural Gas Sector Emission Standards for New, Reconstructed, and Modified Sources at 3-13 (2018); EPA, Regulatory Impact Analysis for the Proposed Revised Cross-State Air Pollution Rule (CSAPR) Update for the 2008 Ozone NAAQS at 5-5 (2020).

⁸⁸ See, e.g., EPA, Draft Guidelines for Preparing Economic Analyses: Review Copy prepare for EPA’s Science Advisory Board at 5-2 (2020), available at <https://perma.cc/3K86-M7AH> (“Limiting standing to citizens and residents of the United States can be complicated to operationalize in practical terms (e.g., how should multinational firms with plants in the United States but shareholders elsewhere be treated?).”).

⁸⁹ *Ctr. for Biological Diversity*, 538 F.3d at 1198.

⁹⁰ RIA at 3-29 n.j. (emphasis added).

domestic-only values in its central analysis of this proposed RIA. To avoid such confusion, EPA should delete that unnecessary reference.

EPA does in fact use those domestic-only estimates in yet another footnote in the RIA. Specifically, note n on page 3-36 explains that those values were incomplete underestimates that ignored how climate impacts occurring outside U.S. borders can directly and indirectly affect U.S. welfare.⁹¹ Nevertheless, EPA presents what the Proposed Rule’s climate benefit would be according to those values, highlighting climate benefits in the years 2023 and 2050. EPA perhaps intended to show that even under such misleadingly low valuations, the proposed standards will still achieve billions of dollars in climate benefits. However, the domestic-only values calculated under the now-revoked Executive Order 13,783 were not simply incomplete and misleading underestimates: they have been ruled by a federal court to be illegally arbitrary values inconsistent with the best available science and economics.⁹² EPA should make even clearer that these values are arbitrary and invalid and should not be relied upon.

At the same time, given past legal challenges to agencies’ reliance on global valuations of the social cost of greenhouse gases, EPA should anticipate there may likely be litigation over its use of the global values in its main analysis here. For example, last year, a judge in the U.S. Court for the District of Wyoming faulted the Bureau of Land Management for not “separately analyzing and reporting the United States’ *domestic* share of [climate] benefits” resulting from a rule to reduce methane waste.⁹³ Even after the agency had explained to the court that there was no suitable methodology for estimating domestic damages, the court opined that “there is no reason to think that a domestic analysis cannot also be performed.”⁹⁴ Thus, notwithstanding all the compelling legal, economic, and policy justifications for focusing on the global values, and despite previous caselaw favorable to the global valuation,⁹⁵ some legal risk remains if EPA relies on global values without conducting a sensitivity analysis using domestically-oriented calculations. Additionally, because EPA included some domestic-only calculations of the social cost of greenhouse gases in its proposed RIA,⁹⁶ erasing any domestic-only calculation from its final RIA could also raise legal challenges.

To further minimize legal risk, therefore, EPA should consider conducting a sensitivity analysis using a domestic-only valuation. The Working Group may in the future release guidance on an appropriate range for such a valuation, and considerable evidence suggests that—after weighing strategic benefits, spillover effects, and extraterritorial interests—any reasonable attempt to estimate the U.S. share of climate benefits would be quite a high proportion of global benefits.⁹⁷ In the meantime, however, the best existing guidance available to EPA for a domestic-only estimate is not the arbitrary values calculated under the now-revoked Executive Order 13,783. Rather, EPA should look to the Working Group’s past technical support documents for guidance.

⁹¹ *Id.* at 3-36 n.n.

⁹² *Bernhardt*, 472 F. Supp. 3d at 613.

⁹³ *Wyoming v. Dept. of the Interior*, 494 F. Supp. 3d 1046, 1080 (D. Wyo. 2020).

⁹⁴ *Id.* at 47.

⁹⁵ See *Zero Zone*, 832 F.3d 654; *Bernhardt*, 472 F. Supp. 3d 573.

⁹⁶ RIA at 3-36 n.n.

⁹⁷ See Schwartz, *supra* note 18, at 39-40 (recommending that a value over 75% could be justified).

In 2010, the Working Group provided an “approximate, provisional, and highly speculative” range of up to 23% of the global value as a domestic-only estimate, but admitted even that was likely a significant underestimate.⁹⁸ Though an imprecise and gross underestimate, those values at least have the virtue of some regulatory precedent, as the Department of Energy has repeatedly used them for sensitivity analyses.⁹⁹ EPA should therefore consider 23% of the global value to be the absolute minimum used for a domestic-only sensitivity analysis. EPA should emphasize that such values are still gross underestimates, as they disregard most of the domestic impacts discussed above including international reciprocity, spillover impacts, and extraterritorial interests. EPA should also note that the integrated assessment models used to estimate the social cost of greenhouse gases were not designed for such localized, non-global estimates. EPA should confirm that, while the Proposed Rule would be cost-benefit justified using such domestic-only values, the agency maintains that the global perspective is the correct focus for its main analysis.

III. EPA Should Provide Additional Justification for Its Discount Rates Choices and Conduct Sensitivity Analysis Using Lower Rates

EPA applies the social cost of greenhouse gas estimates calculated at discount rates of 2.5%, 3%, and 5%,¹⁰⁰ consistent with the Working Group’s current recommendations, and justifies its decision to return to its prior conclusion that a 7% capital-based discount rate is inappropriate for climate effects. While EPA’s return to a reasonable range of discount rates to assess climate impacts is well supported, in anticipation of specious but inevitable legal challenges, EPA should provide additional justifications for its discounting choices.¹⁰¹ EPA should also work to promote consistent language on discounting with the National Highway Traffic Safety Administration’s analysis of its now-proposed vehicle standards and, per the Working Group’s recommendation, EPA should strongly consider providing additional sensitivity analysis around discount rates lower than 2.5%—such as a 2% discount rate.

A. EPA Should Provide Additional Justifications for Its Discount Rate Range

The RIA cites the Working Group’s arguments that, for long-term policies with intergenerational effects, uncertainty and ethical considerations make a 7% capital-based discount rate inappropriate.¹⁰² Though these arguments provide sufficient reason for EPA’s approach to discount rates, because the Working Group’s approach to discount rates—and in particular the reversal of the prior administration’s irrational application of a 7% rate to climate

⁹⁸ Working Group, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis 11* (2010), <https://obamawhitehouse.archives.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf> [“2010 TSD”].

⁹⁹ See, e.g., Dept. of Energy, *Technical Support Document: Energy Efficiency Program for Consumer Products: Residential Central Air Conditioners and Heat Pumps at 14-3 & n.b, 14-6 to 14-7* (2016) (giving preference to calculations based on the global social cost of greenhouse gases, but also including a domestic valuation in sensitivity analysis).

¹⁰⁰ Note that just as there is growing evidence that the discount rate should be below 2%, there is growing evidence that 5% is much too high a discount rate. The values at 5% should be considered a very conservative lower bound.

¹⁰¹ See generally Peter Howard & Jason A. Schwartz, *About Time: Recalibrating the Discount Rate for the Social Cost of Greenhouse Gases* (Policy Integrity Report 2021), https://policyintegrity.org/files/publications/About_Time.pdf

¹⁰² RIA at 3-30.

effects—has already been challenged in court,¹⁰³ EPA should provide additional justifications for its focus on consumption-based rates and its approach to discounting climate effects as compared to other costs and benefits.

1. A 7% Discount Rate Is Inappropriate for Climate Effects, as Considerable Evidence Points to Substantially Lower Discount Rates in Intergenerational Settings

Although *Circular A-4* provides discount rates of 3% and 7% as a default assumption, it also requires agency analysts to do more than rigidly apply default assumptions.¹⁰⁴ As such, analysis must be “based on the best reasonably obtainable scientific, technical, and economic information available,”¹⁰⁵ and agencies must “[u]se sound and defensible values or procedures to monetize benefits and costs, and ensure that key analytical assumptions are defensible.”¹⁰⁶ Rather than assume that a 7% discount rate should be applied automatically to every analysis, *Circular A-4* requires agencies to justify the choice of discount rates for each analysis.¹⁰⁷ Based on *Circular A-4*’s criteria, there are numerous reasons why applying a 7% discount rate to climate effects that occur over a 300-year time horizon would be unjustifiable—and that discount rates of 3% or lower are appropriate.

First, basing the discount rate on the consumption rate of interest (which the 3% rate represents) is the correct framework for analysis of climate effects, whereas a discount rate based on the private return to capital (which the 7% rate represents) is inappropriate. While *Circular A-4* suggests that 7% should be a “default position” that reflects regulations that primarily displace capital investments, it also explains that “[w]hen regulation primarily and directly affects private consumption . . . a lower discount rate is appropriate.”¹⁰⁸ The 7% discount rate is based on a private sector rate of return on capital, as private market participants typically have short time horizons. By contrast, climate change concerns the public well-being broadly rather than market participants narrowly. Rather than evaluating an optimal outcome from the narrow perspective of investors alone, economic theory requires analysts to make the optimal choices based on societal preferences and social discount rates. Moreover, because climate change is expected to mostly affect large-scale consumption, as opposed to capital investment,¹⁰⁹ a 7% rate is inappropriate.

¹⁰⁸ *Id.* at 33.

¹⁰⁹ Maureen Cropper, *How Should Benefits and Costs Be Discounted in an Intergenerational Context?*, 183 *RESOURCES* 30, 33 (2013) (“There are two rationales for discounting future benefits—one based on consumption and the other on investment. The consumption rate of discount reflects the rate at which society is willing to trade consumption in the future for consumption today. Basically, we discount the consumption of future generations because we assume future generations will be wealthier than we are and that the utility people receive from consumption declines as their level of consumption increases. . . . The investment approach says that, as long as the rate of return to investment is positive, we need to invest less than a dollar today to obtain a dollar of benefits in the future. Under the investment approach, the discount rate is the rate of return on investment. If there were no distortions or inefficiencies in markets, the consumption rate of discount would equal the rate of return on investment. There are, however, many reasons why the two may differ. As a result, using a consumption rather than

Crucially, as the Working Group recognizes, the social cost of greenhouse gas estimates present climate damages in consumption-equivalent units, and therefore, *Circular A-4*'s guidance in fact dictates application of consumption-based discount rates.¹¹⁰ The National Academies of Sciences has agreed that a capital-based rate would be inappropriate for use with the social cost of greenhouse gases, given that climate damages are estimated in consumption-equivalent units.¹¹¹ There is also strong consensus through the economic literature that a capital discount rate like 7% is inappropriate for climate change.¹¹²

Second, uncertainty over the long time horizon of climate effects should drive analysts to select a lower discount rate. As an example of when a 7% discount rate is appropriate, *Circular A-4* identifies an EPA rule with a 30-year timeframe of costs and benefits.¹¹³ By contrast, greenhouse gas emissions generate effects stretching out across approximately 300 years. As *Circular A-4* notes, “[p]rivate market rates provide a reliable reference for determining how society values time within a generation, but for extremely long time periods no comparable private rates exist.”¹¹⁴ *Circular A-4* discusses how uncertainty over long time horizons drives the discount rate lower.¹¹⁵ *Circular A-4* cites the work of renowned economist Martin Weitzman and concludes that the “certainty-equivalent discount factor . . . corresponds to *the minimum discount rate having any substantial positive probability*.”¹¹⁶ The National Academies of Sciences makes the same point about discount rates and uncertainty.¹¹⁷

Third, a 7% discount rate also ignores catastrophic risks and the welfare of future generations. As EPA showed in a recent cost-benefit analysis, the 7% rate truncates the long

investment approach will often lead to very different discount rates.”); see also Richard G. Newell & William A. Pizer, Uncertain Discount Rates in Climate Policy Analysis, 32 ENERGY POL’Y 519, 521 (2004) (“Because climate policy decisions ultimately concern the future welfare of people—not firms—the consumption interest rate is more appropriate.”).

¹¹⁷ NAS 2017 Report, *supra* note 111, at 27.

right-hand tail of social costs relative to the 3% rate's distribution.¹¹⁸ The long right-hand tail represents the possibility of catastrophic damages. Thus, the 7% discount rate effectively assumes that present-day Americans are barely willing to pay anything at all to prevent medium- to long-term catastrophes. Given that Congress expressed its overall goal for the Clean Air Act Amendments of 1977 to “insure the protection of the public health and the environment, both of this *and future generations*, while at the same time considering the energy and economic needs of this Nation,” it would not be reasonable for EPA to discount climate impacts at such a high rate as to effectively ignore the welfare of future generations.¹¹⁹

Fourth, long-term time horizons in general counsel strongly against application of a capital-based rate. The Working Group's latest guidance cites Li and Pizer's work on how the capital-based rate is generally inappropriate in many longer-term contexts.¹²⁰ Specifically, Li and Pizer find that, given their best estimate of the shadow price of capital, the appropriate social discount rate collapses to the consumption-based rate relatively quickly, in the span of just several decades.¹²¹ Given the long time horizon that analysis of climate policies demands, the capital-based rate is simply inapplicable.

Fifth, several standard justifications for capital-based discount rates break down given the particular threats of climate change. For example, one argument for capital-based discount rates is that spending capital on climate abatement policies has opportunity costs and so, in policy analysis, future costs and benefits should be discounted at the rate of return to capital. However, the irreversible, uncertain, and catastrophic risks of climate change may disrupt this “opportunity cost” rationale: while it may seem, for instance, that future, wealthier generations might have better opportunities to address climate change for themselves, irreversible or catastrophic damages could arise that make future mitigation efforts more expensive or impossible.¹²² Similarly, if climate damages are “non-marginal,” such that climate change significantly affects the very natural resources needed to drive economic growth, growth could plummet or even turn negative.¹²³

Sixth, a 7% discount rate is inappropriate because it is based on outdated data and diverges from the current economic consensus. *Circular A-4* requires that assumptions—including discount rate choices—are “based on the best reasonably obtainable scientific, technical, and economic information available.”¹²⁴ Yet *Circular A-4*'s own default assumption of a 7% discount rate was published 18 years ago and was based on data from even earlier.¹²⁵ *Circular A-4*'s guidance on discount rates is in need of an update, as the Council of Economic

¹²⁴ *Circular A-4*, *supra* note 72, at 17.

¹²⁵ The 7% rate was based on a 1992 report; the 3% rate was based on data from the 30 years preceding the publication of *Circular A-4* in 2003. *Id.* at 33-34.

Advisers (CEA) detailed recently after reviewing the best available economic data and theory.¹²⁶ CEA gave two reasons to revise the 7% rate, both of which are generally applicable but may have particular force in the context of climate change. The first argument is that the market data clearly shows that the long-term interest rates used to derive the consumption-based discount rates have fallen, such that the 3% consumption-based rate instead “should be at most 2 percent.”¹²⁷ Because of the relationship between long-term, tax-free interest rates and rates of return on capital (i.e., the divergence between those rates is caused largely by taxation), a 1% drop in the consumption-based discount rate strongly suggests a corresponding drop in the capital-based rate.¹²⁸ This may be especially true for longer-term context like climate change, because of the lack of reliable market data to measure expected rates of return on assets held inter-generationally.¹²⁹ The second argument why the 7% rate is too high is that market rates of return are artificially increased by returns associated with unpriced externalities, rents associated with market power, and private (as opposed to social) risk premiums.¹³⁰ For example, a market return on an oil and gas investment is increased because the oil and gas operation can externalize some of the costs of its pollution onto society. Yet especially when crafting long-term climate policies, it would be inappropriate to discount future welfare based on the fact that the current generation of investors prefers the high market returns that are now available partly because of such externalities.¹³¹ As such, the 7% capital-based rate is not only out of date and too high, but especially inappropriate for climate policy.

Finally, *Circular A-4* recognizes that intergenerational contexts raise unique ethical issues that further counsel for lower discount rates. Specifically, it recognizes that “[i]t may not be appropriate for society to demonstrate a similar preference when deciding between the well-being of current and future generations” as it does in the intragenerational setting.”¹³² *Circular A-4* thus recommends that agencies conduct additional analysis at “using a lower [than 3%] but positive discount rate” for impacts with important intergenerational effects.¹³³ Most market data reflects at best individual’s current preferences for their own welfare over time and so simply does not capture society’s preferences toward or ethical obligations to future generations. Basing a discount rate solely on market data ignores such important inter-generational considerations. Executive Order 13,990 instructs agencies to ensure that the social cost of greenhouse gas values adequately account for “intergenerational equity.”¹³⁴ A 7% rate ignores much of future generations’ welfare and so would be inconsistent with that mandate. Notably, even in the SAFE

¹²⁶ CEA Issue Brief, *supra* note 116, at 1; *see also id.* at 3 (“In general the evidence supports lowering these discount rates, with a plausible best guess based on the available information being that the lower discount rate should be at most 2 percent while the upper discount rate should also likely be reduced.”); *id.* at 6 (“The Congressional Budget Office, the Blue Chip consensus forecasts, and the Administration forecasts all place the ten year treasury yield at less than 4 percent in the future, while at the same time forecasting CPI inflation of 2.3 or 2.4 percent per year. The implied real ten year Treasury yield is thus below 2 percent in all these forecasts.”).

rule, EPA and NHTSA explained that the 7% capital rate did not adequately account for “tradeoffs between improving the welfare of current and future generations.”¹³⁵

2. *EPA Should Further Justify Its Distinct Approach to Discounting Climate Effects*

As explained above, EPA’s choice to use the social cost of greenhouse gas values calculated with consumption-based discount rates is fully justified. Two additional discounting choices then arise: how to discount back to present value the application of a future social cost of greenhouse gas value to monetize the climate benefits of future emissions reductions (e.g., bringing the \$85 per ton of carbon dioxide in climate benefits generated by an emissions reduction in the year 2050 back to present value in 2021), and then how to compare those discounted climate effects to other costs and benefits.

EPA has chosen to ensure that all climate benefits are discounted in an internally consistent way, by applying the same discount rate used to estimate the underlying social cost values (e.g., 2.5%, 3%, or 5%) to calculate the present values of future climate benefits.¹³⁶ That approach is consistent with the Working Group’s guidance.¹³⁷ But it also means EPA is calculating the present value of reduced greenhouse gas emissions differently than the present value of other costs and benefits (which, per *Circular A-4*’s current default recommendations, are calculated at 3% and 7% discount rates).¹³⁸

In the future, EPA should consider working with OMB and the Working Group to move toward a declining discount rate framework that can straightforwardly resolve all these issues of consistent discounting, by adopting a single schedule of applicable discount rates that steadily declines over time.¹³⁹ In the meantime, EPA should expand on its justification to its current approach to discounting. EPA should consider two approaches: (1) explaining why a general focus on discounting all costs and benefits at consumption-based rates, rather than at a 7% capital-based rate, is appropriate in this particular rulemaking; and (2) explaining why special legal, economic, and policy considerations justify a different approach to discounting climate effects as distinct from other costs and benefits.

To begin, EPA can explain that given the nature of the Proposed Rule’s costs and benefits, it is more appropriate to discount all effects using consumption-based rates, and so the present value calculations that include some costs and benefits discounted at a 7% rate can be viewed as lower-bound sensitivity analyses. The capital-based discount rate theoretically assesses whether the net benefits from government action will exceed the returns that society could earn by instead investing the same resources in the private sector. But this framework for discounting and comparing benefits and costs makes sense only under the “extreme” assumption that all the costs of government action would “fully displace” (i.e., crowd out) private

¹³⁵ 85 Fed. Reg. at 24,735 (explaining that the central analysis focused on a 3% rate, and the 7% rate was used only for sensitivity analysis).

¹³⁶ 86 Fed. Reg. at 43,735 tbl. 4, note c.

¹³⁷ 2021 TSD, *supra* note 4, at 25 (“[T]he monetized value of future emission changes should be discounted at the same rate used to calculate the initial SC-GHG to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate.”).

¹³⁸ 86 Fed. Reg. at 43,796 tbl. 56, note a.

¹³⁹ See Howard & Schwartz, *supra* note 101, at 41 (recommending a declining discount rate framework).

investment.¹⁴⁰ In this way, the capital-based rate “at best creat[es] a lower bound on the estimate of net benefits,” by applying a maximum discount rate that reflects an extreme case not likely to apply to many government actions.¹⁴¹

In general, there is less of a chance now that U.S. government actions will crowd out private investments than there was in 1992 when OMB first set its 7% capital-based discount rate, because the U.S. economy is relatively more open now.¹⁴² Additionally, the magnitude of the costs and benefits involved in many agency actions will be relatively small compared to the overall U.S. debt, again making it unlikely that agency actions will significantly crowd out private U.S. investment.¹⁴³ Some agency actions may also induce more private investment than they displace.¹⁴⁴ And if the costs of agency actions will be more borne through displaced consumption rather than displaced investment, the crowding-out theory for a capital-based discount rate further breaks down. In this rulemaking, the upfront technology costs and long-term fuel savings will be felt primarily by individual consumers, as will rebound value and refueling time savings; other effects, like health effects, climate benefits, energy security, and congestion, will be felt by society as a whole. In other words, because of the nature of the rule, the theory for a capital-based discount rate has a tenuous application at best. EPA therefore would be justified in arguing for a focus on cost-benefit comparisons using consumption-based rates, with the application of a 7% rate treated like a lower-bound sensitivity analysis.

Separately, EPA would also be justified in taking a distinct approach to discounting climate effects, and EPA should elaborate on the special legal, economic, and policy considerations. While effects like fuel savings and energy security will play out over the course of the next several decades, the climate effects of this rule are undeniably much longer term, affecting the welfare of future generations over centuries. Therefore, the arguments in favor of lower consumption-based discount rates—based on long-term uncertainty, ethics, declining economic growth, inapplicable market data, and other considerations—apply much more strongly to climate effects than to other costs and benefits. And because a high capital-based rate, like 7%, will effectively ignore the welfare of future generations (e.g., over the course of just 80 years, a 7% rate discounts away 99.5% of a future effect’s value¹⁴⁵) legal requirements to consider the welfare of future generations caution much more strongly against the application of a 7% rate to long-term climate effects than to other costs and benefits. Notably, the Clean Air Act Amendments of 1977 expressed the congressional goal to “insure the protection of the public health and the environment, both of this *and future generations*,”¹⁴⁶ and NEPA broadly instructs¹⁴⁷ all agencies to interpret all their laws to the fullest extent possible to advance the

¹⁴³ *Id.*

¹⁴⁴ 2021 TSD, *supra* note 4, at 19 (noting that if the social returns to induced investments have not been quantified, using a capital-based discount rate “is not even a lower bound”).

¹⁴⁵ The discount factor is $\frac{1}{(1+r)^t}$; $\frac{1}{(1+0.07)^{80}} = 0.0045 = 0.45\%$.

¹⁴⁶ H.R. Rep. No. 95-294, 34, 1977 U.S.C.C.A.N. 1077, 1112; *see also* Howard & Schwartz, *supra* note 101, at 32 (summarizing the Clean Air Act’s legislative history and references to future generations).

¹⁴⁷ Note again that these NEPA provisions apply outside the context of conducting environmental impact statements for major actions, and so EPA’s exclusion under the Clean Air Act does not apply.

national environmental policies,¹⁴⁸ including to “fulfill the responsibilities of each generation as trustee of the environment for succeeding generations.”¹⁴⁹ Multiple Executive Orders, including Executive Order 13,563 and 13,990, also call for agencies to appropriately and accurately weigh the interests of future generations.¹⁵⁰

Consequently, as the National Academies of Sciences has recognized, some differences in the application of discount rates may be warranted “when only some categories [of costs and benefits] have an intergenerational component.”¹⁵¹ The National Academies has offered recommendations for how agencies can best apply different annualized discount rates to climate impacts versus other costs and benefits,¹⁵² and EPA can rely on the National Academies’ guidance to support its approach to discounting here.

Case law on the social cost of greenhouse gases also offers support for EPA’s discounting approach. Specifically, in *Zero Zone v. Department of Energy*, the plaintiffs argued that the Department of Energy had arbitrarily considered hundreds of years of climate benefits while limiting its assessment of employment impacts and other effects to just a thirty-year time horizon. The court upheld the regulatory analysis, concluding that the difference in time horizons was justified because the rule “would have long-term effects on the environment but . . . would not have long-term effects on employment.”¹⁵³ The choice of time horizons is related to the choice of discount rate: any cost or benefit occurring beyond the end of the analytical time horizon is effectively discounted at an infinitely high (or 100 percent) rate.¹⁵⁴ Analogizing from this precedent, a court may similarly defer to an agency’s finding that the long time horizon of climate change justifies a lower discount rate than the rate applied to shorter-term costs and benefits. EPA should explain the special economic, legal, and ethical considerations that justify selecting a different annual discount rate for climate effects than for other costs and benefits.

B. EPA Should Conduct Additional Sensitivity Analysis Around Lower Discount Rates for Climate Impacts

In its regulatory impact analysis for the Proposed Rule, EPA assesses climate benefits using discount rates of 2.5, 3, and 5 percent for the social cost of greenhouse gases. In its most recent technical support document, however, the Working Group suggested that agencies “conduct[] additional sensitivity analysis using discount rates below 2.5 percent.”¹⁵⁵ And while EPA repeatedly references the fact that considering discount rates at “2 percent and lower” is “warranted,”¹⁵⁶ EPA’s list of sensitivity analyses does not include a run using a 2% or lower

discount rate for the social cost of greenhouse gases.¹⁵⁷ Because of the considerable evidence that the most appropriate discount rate should be below 2%, and in anticipation of potential future updates to the Working Group’s recommendations, EPA should conduct additional sensitivity analysis around lower discount rates for the social cost of greenhouse gases, including discount rates of 2% or lower.

As the Working Group explained in its recent technical support document, there is considerable evidence from market data that the default estimate of the consumption-based discount rate should be revised down from 3% to 2%. In the context of long-term, intergenerational effects like climate damages, the case for a lower discount rate is even stronger, in light of ethical considerations and other factors.¹⁵⁸ Multiple expert elicitations show a growing consensus around a discount rate below 2%,¹⁵⁹ and factors like uncertainty, negative economic growth correlations, risk aversion, and the scarcity and non-substitutability of environmental goods all point strongly toward even lower discount rates.¹⁶⁰

For this reason, among others, the Working Group acknowledged in its latest technical support document that its social cost valuations—presented at discount rates of 2.5%, 3%, and 5%—“likely underestimate societal damages from [greenhouse gas] emissions.”¹⁶¹ The Working Group will evaluate the discount rate (among other issues) as it performs a full assessment of its social cost valuations to reflect the latest scientific and economic research—a task that it has been ordered to complete by January 2022.¹⁶² In the meantime, the Working Group has recommended that agencies apply additional sensitivity analysis around lower discount rates.¹⁶³ To do so, EPA could look to the “value of carbon” estimates from the New York State Department of Environmental Conservation (“DEC”), which applied a 2% discount rate as its central value.¹⁶⁴ Pursuant to DEC’s estimates, at a discount rate of 2% social cost valuations for year 2020 emissions equal \$125 per ton of carbon dioxide, \$2,782 per ton of methane, and

¹⁵⁹ Peter Howard & Derek Sylvan, *The Economic Climate: Establishing Expert Consensus on the Economics of Climate Change*, INST. POLICY INTEGRITY WORKING PAPER 33–34 (2015); M.A. Drupp, et al., *Discounting Disentangled: An Expert Survey on the Determinants of the Long-Term Social Discount Rate* (London School of Economics and Political Science Working Paper, May 2015) (finding consensus on social discount rates between 1–3%). Pindyck, in a survey of 534 experts on climate change, finds a mean discount rate of 2.9% in the climate change context and this rate drops to 2.6% when he omits individuals that lack confidence in their knowledge. Robert S. Pindyck, *The Social Cost of Carbon Revisited* (National Bureau of Economic Research, 2016). Unlike Howard and Sylvan (2015), Pindyck (2016) combines economists and natural scientists in his survey, though the mean constant discount rate drops to 2.7% when including only economists. Again, this further supports the finding that the appropriate discount rate is below 3%.

¹⁶⁰ *See, e.g.*, Howard & Schwartz, *supra* note 101, at 10 (reporting such research and concluding that “the best empirical estimate of the discount rate based on long-term interest rates in the current period is under 1%—and is likely to remain under 2% or less for the foreseeable future”); *See also* Drupp et al., Comments on Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990 (June 20, 2021).

\$44,727 per ton of nitrous oxide.¹⁶⁵ DEC also recommended using a 1% discount rate for climate impacts, and provided annual social cost values for doing so.¹⁶⁶ Because these valuations are based off of the Working Group’s methodology, and differ only through the discount rate, EPA can apply these valuations if it applies additional sensitivity analysis around lower discount rates.

C. EPA Should Ensure Analytical Consistency With the Treatment of Climate Benefits in NHTSA’s Concurrent Fuel-Economy Rulemaking—Though Consistent Approaches Need Not Be Identical Approaches

While EPA and NHTSA both assess global climate benefits using discount rates of 2.5%, 3%, and 5% in their recently proposed vehicle rules,¹⁶⁷ there is a slight difference in the analyses between the two agencies. Many but not all of EPA’s summary tables focus on the social cost of greenhouse gas values calculated at a 3% discount rate,¹⁶⁸ though EPA does caution against interpreting the 3% values as its “central” estimates.¹⁶⁹ By comparison, NHTSA tends to focus more on climate benefits calculated at a 2.5% discount rate in its summary tables, though again NHTSA does apply the Working Group’s full range of values. These two approaches are consistent with each other and with the Working Group’s guidance, which reminds agencies of their discretion to focus on lower discount rates.¹⁷⁰ Nevertheless, because the approaches are not identical, they could be misinterpreted in ways that could wrongly cast doubt on the social cost of greenhouse gas values. To reduce legal risk, EPA and NHTSA should strive for analytical consistency in the treatment of climate benefits as they finalize their regulations.

Although there are few cases addressing an agency’s discount rate in a cost-benefit analysis, courts have usually been reluctant to second-guess an agency’s discounting choice in the instances where it has been challenged. In one case, for example, the U.S. Court of Appeals for the District of Columbia Circuit deferred to an agency’s discount rate selection as “first and foremost a policy choice,” and explained that the agency was free to revisit its discount rates in future rulemakings “so long as it sets forth a reasonable justification for doing so.”¹⁷¹ This decision fits squarely within the judiciary’s deferential approach to reviewing the more technical aspects of an agency’s cost-benefit analysis.¹⁷²

¹⁷² See, e.g., *Am. Petroleum Inst. v. EPA*, 862 F.3d 50, 69 (D.C. Cir. 2017), *decision modified on reh’g*, 883 F.3d 918 (D.C. Cir. 2018) (explaining that an agency “is free to rely on theoretical or model-based approaches, as long as that reliance is reasonable in context” and there is “some indication of a reasonable concurrence between model and reality”).

Given all of the evidence discussed above pointing to relatively low discount rates in intergenerational contexts, agency reliance on a 3% or 2.5% discount rate for the social cost of greenhouse gases—or even a lower discount rate consistent with the latest evidence—should easily meet the applicable standard of review. Agencies generally are given broad deference in selecting technical valuations, as noted above, and different agencies have sometimes used different inputs for key metrics such as the statistical value of life (i.e. the monetary value placed on mortality risks).¹⁷³ Consistent with this precedent, EPA and NHTSA should be able to rationally justify reliance on different discount rates for the social cost of greenhouse gases.

But such a strategy does not come without risk. Though deference to technical valuations is broad, a court may invalidate a regulation if a key analytical input is insufficiently explained or inconsistent with evidence and practice. Should EPA and NHTSA apply different discount rates in their analyses, critics could point to such an alleged inconsistency in an attempt to misleadingly argue that the social cost of greenhouse gases is indeterminate or arbitrary. More problematically, critics could point to statements made by each agency to justify its preferred discount rate to argue that the other agency’s choice is irrational. To the extent that EPA and NHTSA can agree on more consistent presentations and discussions about the discount rate, it may help minimize the risk of such misinterpretations. EPA should especially be careful not to use any language that could be taken out of context to misleadingly criticize NHTSA’s approach.

But ultimately, consistency does not require identical approaches. Both agencies have considered the full range of values recommended by the Working Group, and the choice to focus in some summary tables on the values calculated either at 3% or 2.5%—or even at lower values, like 2%—can be fully justified.

IV. EPA Should Defend Against Common Criticisms of the Working Group’s Methodology

While the Working Group developed its social cost valuations through a rigorous process that incorporated the best scientific and economic modeling available at the time, its assumptions have sometimes been criticized by opponents of climate regulation. Such objections lack legal merit, and do not supply bases for EPA to reject the Working Group’s expert valuations. Nonetheless, in order to minimize legal risk, EPA should provide additional defense of the Working Group’s process and modeling assumptions, and be prepared to respond to common criticisms of its work. This section offers a defense of the Working Group’s process and methodology, and offers responses to common criticisms that have been offered by opponents of strong climate policy.

A. The Working Group’s Methodology Is Rigorous, Transparent, and Based on a Range of Assumptions Reflecting the Best Available Data

Although the term “social cost of greenhouse gases” is often used synonymously with the valuations developed by the federal Working Group, economic research and modeling on the social cost of greenhouse gases predate federal efforts to monetize incremental climate damages.

¹⁷³ Cong. Research Serv., *How Agencies Monetize “Statistical Lives” Expected to Be Saved By Regulations* 36 (2010) (“The [values of a statistical life] that agencies used in their regulatory impact analyses were generally somewhat similar, with most agencies using central values ranging from about \$5.0 million to \$8.0 million (in 2009 dollars). Agencies sometimes did sensitivity analyses using VSLs as low as \$3 million and as high as \$10 million. One study suggested that DHS conduct sensitivity analyses using values as high as \$12.6 million.”). *See also id.* at 31 tbl. 3 (cataloguing VSL values applied by rule).

Several of the most celebrated economic models of climate damages—such as models by William Nordhaus¹⁷⁴ and Chris Hope¹⁷⁵ that have since been integrated into the federal government’s damage valuations—were first released in the early 1990s.

Owing to the availability of these damage models, the U.S. Court of Appeals for the Ninth Circuit held in 2008 that the federal government must monetize climate impacts when it conducts a cost-benefit analysis. In *Center for Biological Diversity v. National Highway Traffic Safety Administration*, the Ninth Circuit remanded a fuel economy rule to the Department of Transportation (“DOT”) for failing to monetize the benefits of carbon dioxide reductions in its regulatory analysis.¹⁷⁶ The Court recognized the presence of uncertainty in the valuation of climate damages, but explained that “the value of carbon emissions reduction is certainly not zero.”¹⁷⁷ By failing to value the benefit of greenhouse gas emission reductions in its analysis, the Court continued, DOT effectively ignored the adverse impacts of greenhouse gas emissions and thus “put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards.”¹⁷⁸

Following this decision, federal agencies began applying different valuations of the social cost of greenhouse gases in their regulatory analyses.¹⁷⁹ To harmonize those damage valuations across agencies, the Obama administration convened an interagency working group comprised of members of twelve federal agencies and departments, including EPA, the Council of Economic Advisors, Office of Management and Budget, the Department of Energy, and DOT.¹⁸⁰ The Working Group released its first estimates of the social cost of carbon (i.e. carbon dioxide) in 2010,¹⁸¹ which it updated in both 2013¹⁸² and 2016¹⁸³ to incorporate more recent scientific and economic data. Following its 2013 update, the Working Group also solicited comments on its social cost estimates,¹⁸⁴ resulting in a 44-page document with detailed responses to the

¹⁷⁴ The earliest versions of Nordhaus’s DICE model were published starting in 1992. See William Nordhaus, *An Optimal Transition Path for Controlling Greenhouse Gas Emissions*, 258 *SCIENCE* 1315 (1992).

¹⁷⁵ Chris Hope first released his PAGE model in 1991. comments received.¹⁸⁵ The Working Group also released damage estimates for two other greenhouse gases—methane and nitrous oxide—in 2016.¹⁸⁶ These additional metrics used the same economic models, the same treatment of uncertainty, and the same methodological assumptions that the Working Group applied to the social cost of carbon, and underwent peer review.¹⁸⁷

B. EPA Is Required to Value Climate Damages, and Doing So Provides Balance to EPA’s Cost-Benefit Analysis

One objection to agency usage of the Working Group’s estimates is that Congress, not the executive branch, should set policy with respect to climate change. But EPA has broad authority to assess climate impacts, and judicial precedent suggests that it must value climate-change impacts as part of its regulatory impact analysis. In fact, assessing climate damages as part of its regulatory impact analysis provides rationality and balance to EPA’s approach—and does not, as critics have suggested, inappropriately skew the analysis.

1. EPA Must Monetize Climate Impacts as Part of Its Analysis

It is widely established that federal agencies may—and often must—consider effects on climate change when those effects flow from the agency’s actions. With EPA, this is especially well-established. Perhaps most relevant here, in *Massachusetts v. EPA*, the Supreme Court held that EPA may regulate greenhouse gas emissions from new motor vehicles.¹⁸⁸ Because the purpose of the Proposed Rule is to limit greenhouse gas pollution from new motor vehicles—directly in line with the *Massachusetts* precedent—EPA should naturally and obviously consider impacts on climate when deciding upon the stringency of its regulation.

Since EPA must account climate impacts, therefore, the only relevant question is how it should account for those impacts. Monetizing climate impacts is the best available option. Indeed, it is well accepted in regulatory practice and precedent that agencies should monetize regulatory impacts to the extent feasible, in order to compare costs and benefits along a common metric and select the alternative that maximizes net benefits.¹⁸⁹ In a decision that sparked the federal government to develop consensus valuations of climate damages in the first place—the *Center for Biological Diversity* case discussed above—the Ninth Circuit held that the Department of Transportation acted arbitrarily and capriciously by failing to monetize potential climate benefits when assessing the costs and benefits of various alternative fuel-economy

¹⁸⁹ Circular A-4, *supra* note 72, at 2 (“Benefit-cost analysis is a primary tool used for regulatory analysis.2 Where all benefits and costs can be quantified and expressed in monetary units, benefit-cost analysis provides decision makers with a clear indication of the most efficient alternative, that is, the alternative that generates the largest net benefits to society (ignoring distributional effects).”).

standards for new automobiles.¹⁹⁰ And EPA monetized climate damages both in the SAFE Rule and in the Section 202 emissions standards promulgated under the Obama administration.

2. Monetizing Climate Benefits Does Not Skew the Analysis, but Rather Provides Balance Since EPA Also Monetizes Costs

Another objection to the use of the social cost of greenhouse gases from critics of climate action is that these valuations account only for the damages from climate change, but do not take account of the economic benefits from fossil-fuel production and usage, such as economic development and employment. But this argument is unpersuasive for two key reasons.

First, the economic benefits of fossil-fuel extraction are far more limited than its proponents suggest, since the broader benefits that society derives from power and electricity are attributable to energy production in general and are not unique to fossil fuels.¹⁹¹ Accordingly, controls on fossil fuels will hasten a transition to a greener economy, and so have limited net economic impacts.¹⁹² Second, while there are of course some economic impacts from reductions in fossil-fuel production and usage, including effects on revenues and jobs, those impacts should not be included in any calculation of climate damages, but rather considered separately by regulators on the costs side of the ledger in individual determinations.

In the Proposed Rule, EPA monetizes not only the expected benefits of the proposal—including, but not limited to, climate benefits—but also the expected compliance costs from industry as well as other costs of the rule such as expected fatalities, forgone consumer surplus, and even noise costs. EPA then compares quantified cost and benefit estimates in determining whether and how to regulate, as instructed by federal guidance and executive order.¹⁹³ Capturing climate benefits is thus essential to ensuring a balanced analysis. As the Ninth Circuit has held, “failure to monetize the most significant benefit of more stringent [vehicle-emission] standards: reduction in carbon emissions”—while continuing to value estimated compliance costs—would “put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards.”¹⁹⁴

¹⁹⁰

¹⁹¹ Renewable energy, like fossil fuels, generates revenue, supports jobs, and vitalizes local economies. *See, e.g.,* Katie Siegner et al., Rocky Mtn. Inst., *Seeds of Opportunity: How Rural America Is Reaping Economic Development Benefits from the Growth of Renewables* 6–16 (2021), available at <https://perma.cc/DWH9-D4L7>.

¹⁹² Environmental regulation typically has limited impacts on total employment or other macroeconomic indicators, but rather shifts production from one sector to another. *See* Inst. for Pol’y Integrity, *Does Environmental Regulation Kill or Create Jobs* (2017), available at https://policyintegrity.org/files/media/Jobs_and_Regulation_Factsheet.pdf. Meanwhile, the sharp decline in the cost renewable energy is already expected to crowd out the demand for gas-fuel electricity in the coming years and decades. *See, e.g.* Energy Info. Admin., *Annual Energy Outlook 2021 Narrative* 18 tbl. 11 (projecting doubling of renewables as a share of domestic energy consumption—from 21% to 42%—by 2050 under reference case, while share of coal and natural gas declines); Charles Teplin et al., ROCKY MTN. INST., *The Growing Market for Clean Energy Portfolios* 8 fig. ES-2 (2019), available at <https://perma.cc/P5YJ-WARJ> (showing precipitous decline in cost of clean energy to being cheaper than fossil fuels).

¹⁹³ Exec. Order No. 12,866 § 1(a), 58 Fed. Reg. 51,735 (Oct. 4, 1993) (directing that “in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits”).

C. Common Criticisms of the Working Group’s Methodology from Opponents of Climate Policy Lack Merit

EPA should also provide detailed responses to any objections lobbed against the Working Group’s methodology and valuations during this comment period. The Working Group, of course, has already responded to criticisms of its methodology that were offered during the public comment period that it held in 2013,¹⁹⁵ and EPA should draw from that document where relevant in responding to objections offered through this notice-and-comment process. But some objections are now being raised that were not offered during the 2013 comment period, while some of the responses that the Working Group provided can be supplemented with more recent information. Below, we provide brief responses to common objections that are now being presented by opponents of climate reforms.

1. *The Social Cost Valuations Are Not Too Uncertain to Apply*

While critics argue that there is too much uncertainty to rely on the Working Group’s social cost valuations, this argument is incorrect on multiple levels. As a legal matter, the presence of some uncertainty in the social cost valuations should not preclude agencies from using the best numbers available. And as a factual matter, the Working Group rigorously considered uncertainty and accounted for it in numerous ways. If anything, the presence of continued uncertainty suggests that the social cost valuations should be higher than presently valued—not that climate damages should be ignored.

Federal courts have repeatedly recognized that agency analysis necessitates making predictive judgments under uncertain conditions, explaining that “[r]egulators by nature work under conditions of serious uncertainty”¹⁹⁶ and “are often called upon to confront difficult administrative problems armed with imperfect data.”¹⁹⁷ As the Ninth Circuit has explained, “the proper response” to the problem of uncertain information is not for the agency to ignore the issue but rather “for the [agency] to do the best it can with the data it has.”¹⁹⁸ Courts generally grant broad deference to agencies’ analytical methodologies and predictive judgments so long as they are reasonable, and do not require agencies to act with complete certainty.¹⁹⁹

Use of the Working Group’s social cost estimates is precisely the type of reasonable analysis of uncertain information that courts endorse. The Working Group rigorously considered various sources of long-term uncertainty “through a combination of a multi-model ensemble, probabilistic analysis, and scenario analysis.”²⁰⁰ As the Working Group explained, the three IAMs account for uncertainty themselves by spanning a range of economic and ecological outcomes.²⁰¹ Additionally, the use of three separate models—all developed by different experts

²⁰⁰ 2021 TSD, *supra* note 4, at 26.

²⁰¹ *See id.*

spanning a range of views—accounts for uncertainty by integrating a diversity of viewpoints and structural and analytical considerations.²⁰²

In addition to the use of three distinct damage models with differing inputs and assumptions, the Working Group integrated various sources of uncertainty into its damage valuations. For instance, the Working Group applied an equilibrium climate sensitivity—that is, an estimate of how much an increase in atmospheric greenhouse gas concentrations affects global temperatures—that reflects a broad distribution of possible outcomes.²⁰³ The Working Group also applied five different socioeconomic and emissions trajectories from the published literature reflecting a range of possible outcomes for future population growth, global gross domestic product, and greenhouse gas emission baselines—all important inputs that affect long-term climate damage estimates.²⁰⁴ The Working Group ran each integrated assessment model 10,000 times per scenario (and per greenhouse gas) for a total of 150,000 draws per greenhouse gas, and then averaged across those results to develop its recommended estimates.²⁰⁵ In addition to reporting the average valuations, the Working Group published the results of each model run under each scenario.²⁰⁶

Moreover, experts broadly agree that the presence of uncertainty in the social cost valuations counsels for more stringent climate regulation, not less.²⁰⁷ This is due to various factors including risk aversion, the informational value of delaying climate change impacts, and the possibility of irreversible climate tipping points that cause catastrophic damage.²⁰⁸ In fact, as discussed above, uncertainty is a factor justifying lowering the discount rate, particularly in intergenerational settings.²⁰⁹ Furthermore, current omission of key features of the climate problem such as catastrophic damages and certain cross-regional spillover effects further suggests that the true social cost values are likely higher than the Working Group’s current estimates.²¹⁰

²⁰² See *id.*

²⁰⁷ See, e.g., Alexander Golub et al., *Uncertainty in Integrated Assessment Models of Climate Change: Alternative Analytical Approaches*, 19 ENV’T MODELING & ASSESSMENT 99 (2014) (“The most important general policy implication from the literature is that despite a wide variety of analytical approaches addressing different types of climate change uncertainty, none of those studies supports the argument that no action against climate change should be taken until uncertainty is resolved. On the contrary, uncertainty despite its resolution in the future is often found to favor a stricter policy.”).

²⁰⁸ The undersigned organizations have filed comments in numerous regulatory proceedings highlighting the various forms of uncertainty that increase the social cost of greenhouse gases, and providing numerous references. See, e.g., Environmental Defense Fund et al., *Improper Valuation of Climate Effects in the Proposed Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS*, Technical App’x: Uncertainty (Dec. 14, 2020), https://policyintegrity.org/documents/Joint_SCC_comments_EPA_revised_CSAPR_Ozone_NAAQS_2020.12.14.pdf.

²⁰⁹ See Howard & Schwartz, *supra* note 101, at 13–25.

²¹⁰ See 2016 TSD, *supra* note 183, at 21 (recognizing that “these limitations suggest that the [social cost of greenhouse gases] estimates are likely conservative”).

2. *The Working Group Did Not Bias Its Estimates by Ignoring Positive Impacts of Climate Change*

Critics further claim that the Working Group’s social cost values ignore important positive impacts of a warming climate. Examples that have been offered to support this argument include alleged agricultural benefits from higher temperatures and decreased wintertime mortality. But these arguments are legally and factually dubious, and miss the forest for the trees.

Mere omission of some impacts does not counsel for abandoning the social cost estimates, particularly since independent experts widely agree that those estimates likely undervalue true climate damages because they omit far more negative effects than positive ones. For instance, the Working Group has explained that several of the underlying economic models omit certain major damage categories such as catastrophic damages and certain cross-regional spillover effects.²¹¹ These effects can be massive: One paper, for instance, finds that the inclusion of tipping points doubles the social cost estimates,²¹² with another paper concluding that the effect is even greater and thus the Working Group’s existing values “may be significantly underestimating the needs for controlling climate change.”²¹³ The current consensus of experts puts damages for a 3°C increase at roughly 5% to 10% of gross domestic product,²¹⁴ which is substantially higher than the damages estimated by the IAMs.²¹⁵ And as the Ninth Circuit has explained, the presence of some omitted damages does not provide a legal basis to ignore established methodologies to monetize climate damages, since while “there is a range of [plausible] values, the value of carbon emissions reduction is certainly not zero.”²¹⁶

In addition to its legal shortcomings, arguments about the impact of positive externalities are also factually suspect. For instance, while agricultural benefits have become a flashpoint in this debate, the IAMs in fact do account for the potential agricultural benefits of carbon dioxide fertilization from a warming planet.²¹⁷ And evidence suggests that, if anything, these models overvalue agricultural benefits from a warming planet—and thus undervalue the social cost of greenhouse gases.²¹⁸ One paper, for instance, concludes that estimates of net agricultural impacts

²¹⁸ See, e.g., Frances C. Moore et al., *Economic Impacts of Climate Change on Agriculture: A Comparison of Process-Based and Statistical Yield Models*, 12 ENV’T RES. LTRS., 65008 (“[W]e find little evidence for differences in the yield response to warming. The magnitude of CO₂ fertilization is instead a much larger source of uncertainty.

produced an undervaluation of the social cost of carbon by more than 50%, explaining that “new damage functions reveal far more adverse agricultural impacts than currently represented” in the IAMs used by the Working Group.²¹⁹ And a comprehensive investigation of the impacts of climate change on agriculture has rejected the hypothesis “that agricultural damages over the next century will be minimal and indeed that a few degrees Celsius of global warming would be beneficial for world agriculture,” concluding that climate change “will have at least a modest negative impact on global agriculture in the aggregate.”²²⁰

Other arguments focusing on omitted positive impacts are equally misguided. For example, while some critics of the Working Group’s methodology misleadingly point out that one of the models, DICE, focuses on increased heat-related mortality and does not account for reductions in wintertime mortality, consideration of the many damages omitted from the IAMs (such as particulate matter from wildfires, deaths from flooding, Lyme and other tick-based diseases), including certain mortality effects, consistently point toward a higher social cost value.²²¹ One recent study, in fact, concludes that the IAMs, on net, undervalue mortality from climate change.²²² Focusing on the omission of reductions in wintertime mortality thus misses the forest for the trees, and does not supply a basis to disregard the Working Group’s valuations.

3. *The Working Group Did Not Overstate the Pace of Climate Change*

Critics further allege that the chosen Equilibrium Climate Sensitivity (“ECS”) distribution—that is, the amount of warming that is expected to result from a doubling of the atmospheric carbon dioxide concentration—is outdated and fails to account for recent evidence showing that sensitivity to be lower than previously believed. But these arguments rely on cherry-picked data and ignore the scientific consensus.

In 2016, the National Academies of Sciences dedicated an entire report to whether the Working Group should update the social cost metrics to reflect more recent science on the ECS. The National Academies decided that such an update was unnecessary, “recommend[ing] against a near-term change in the distributional form of the ECS” and explaining that any reasonable revisions on this front would “have a minimal impact on estimates of the [social cost of greenhouse gases].”²²³

Based on this set of impact results, we find a very limited potential for on-farm adaptation to reduce yield impacts.”).

Chicago, Becker Friedman Institute for Economics Working Paper No. 2018-51) (Jul. 31, 2019), https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3224365 (finding that new empirical estimates suggest that the increase in mortality risk from climate change is valued at approximately 3.2% of global GDP in 2100).

²²³ Nat’l Acad. Scis., Eng’g & Med., *Assessment of Approaches to Updating the Social Cost of Carbon: Phase 1 Report on a Near-Term Update* 34, 46 (2016), available at <https://perma.cc/TJM6-XE65> [hereinafter “NAS 2016 Report”].

On top of the National Academies' rejection of this argument, there is little support for the claim that the Working Group overstated the pace of climate change. The most recent estimate from the Intergovernmental Panel on Climate Change ("IPCC")—which reflects consensus estimates from the worldwide scientific community—projects an ECS range from 2.5°C to 4°C, with 3°C as a "best estimate."²²⁴ This is consistent with the range applied by the Working Group—based off of Roe & Baker—which uses 3°C as its median and 3.5 °C as its mean ECS value.²²⁵ In evaluating the ECS, the Working Group assessed estimates from a wide range of experts and selected consensus values. In fact, as the Working Group acknowledged, some ECS estimate ranges go as high as 10° C, making its selected ECS distribution substantially lower than these high-end estimates and a reasonable middle range.²²⁶

Critics further argue that the ECS distribution applied by the Working Group inappropriately skews rightward, meaning that its mean ECS value exceeds the median value of 3° C that the IPCC has indicated. But that decision is a feature, not a bug. As the National Academies explained, the IPCC has found that there is a "positively skewed distributional form for [the ECS] parameter" similar to the ECS distribution applied by the Working Group.²²⁷ In other words, the mean ECS value should be higher than the median ECS value, and the Working Group applied an appropriate distribution. Criticisms to the contrary are meritless.

4. *The Working Group Applied a Reasonable Range of Emission Baselines*

Critics further argue that the Working Group's valuations are an overestimate because they apply outdated emission scenarios that exaggerate the baseline level of atmospheric greenhouse gas levels. Using a higher baseline level of emissions raises the social cost estimates because the harm from an additional unit of emissions increases with the baseline atmospheric emissions level. However, the Working Group used a reasonable emissions baseline that reflects different possible mitigation scenarios.

While the Working Group assumed a baseline emissions range of 13–118 gigatons of carbon dioxide emitted per year by 2100,²²⁸ recent projections from the Climate Action Tracker indicate that baseline emissions will reach between 14–175 gigatons of carbon dioxide by 2100 under a range of scenarios reflecting different levels of mitigation.²²⁹ Thus, the baselines used by the Working Group potentially understate baseline emissions rather than overvalue them as opponents argue. In fact, several of the Working Group's supposedly "business-as-usual" scenarios are actually more consistent with baseline estimates reflecting policy projections.²³⁰ Accordingly, the criticism that the Working Group overestimated future greenhouse gas concentrations in the atmosphere falls flat.

²³⁰ Compare *id.* (projecting 35-48 gigatons of emissions in 2100 under "current policy projections" scenarios and 83-175 gigatons under business-as-usual scenario) with 2010 TSD, *supra* note 98, at 16 tbl.2 (incorporating supposedly business-as-usual scenarios of 42.7 and 60.1 gigatons in 2100).

Moreover, this choice does not particularly affect the social cost valuations. In comparison to the Working Group’s central social cost of carbon estimate in 2020 of \$51 per ton, the average social cost of carbon under the Working Group’s supposed business-as-usual emissions scenarios is \$53 per ton and \$41 per ton under the emissions scenario that is consistent with sustained and widespread mitigatory action.²³¹ While relying less on the Working Group’s supposed business-as-usual scenarios would therefore modestly decrease the interim social cost valuations in a vacuum, more holistic updates to the metrics as recommended by the National Academies of Sciences would very likely increase the social cost valuations overall due to the omitted damages discussed above and recent evidence regarding intergenerational discount rates.²³² At best, therefore, this argument makes a mountain out of a molehill.

5. *The Working Group Applied Scientifically-Based Damage Models*

Critics further claim that the IAMs—the damage functions for translating climate impacts into economic losses—are flawed and arbitrary. In reality, however, the damage functions are based on reasonable assumptions made by a range of experts.²³³ They have also withstood scientific scrutiny, and while opponents of climate reform frequently highlight criticism of the damage functions by a notable economist, they take this criticism out of context.

The Working Group selected three models of climate damages that were the most widely used and cited models in the economics literature linking physical climate impacts to economic damages²³⁴: the DICE, FUND, and PAGE models.²³⁵ These models were developed by outside experts, published in peer-reviewed economic literature,²³⁶ and were the product of extensive scholarship and expertise. One of the models, DICE, was developed by William Nordhaus, an economics professor and former provost of Yale university who won a Nobel Memorial Prize in Economic Sciences for developing the model. And PAGE developer, Chris Hope, was a lead author and review editor for the Third and Fourth Assessment Reports of the IPCC, which shared the Nobel Peace Prize in 2007 with former U.S. Vice President Al Gore.²³⁷

The three models reflect a wide diversity of methodological assumptions about a range of key parameters and inputs.²³⁸ This reflects, in part, different judgments about the experts who developed the models. For instance, Richard Tol, who developed the FUND model, has stated

²³¹ See Peter Howard et al., *Option Value and the Social Cost of Carbon: What Are We Waiting For?* (Inst. for Pol’y Integrity Working Paper No. 2020/1) at 16 tbl.1 (2020), available at https://policyintegrity.org/files/publications/Working_paper_06.22.20.pdf.

²³² See 2021 TSD, *supra* note 4, at 4 (Working Group acknowledging that its current social cost valuations “likely underestimate societal damages from [greenhouse gas] emissions”).

²³³ Response to Comments, *supra* note 113, at 8 (“While the development of the DICE, FUND and PAGE models necessarily involved assumptions and judgments on the part of the modelers, the damage functions are not simply arbitrary representations of the modelers’ opinions about climate damages.”).

²³⁴ Response to Comments, *supra* note 113, at 4 (stating the models “remain the most widely cited”), 8 (quoting the National Academies of Sciences for recognizing that the chosen models represent “the most widely used impact assessment models” available).

²³⁵ 2010 TSD, *supra* note 98, at 5.

²³⁶ Response to Comments, *supra* note 113, at 4.

²³⁷ See Chris Hope faculty bio page, University of Cambridge Judge Business School, <https://www.jbs.cam.ac.uk/faculty-research/research-teaching-staff/chris-hope/> (last visited Sept. 24, 2021).

²³⁸ See 2010 TSD, *supra* note 98, at 6 (discussing how “[t]he parameters and assumptions embedded in the three models vary widely”).

that “[t]he impact of climate change is relatively small,” and dismissed much of the research behind climate change as “scaremongering” rather than “sound science.”²³⁹ Unsurprisingly, his model produces the lowest damage estimates of the three models incorporated by the Working Group.²⁴⁰ William Nordhaus, who developed the DICE model, is widely credited with popularizing the goal that global temperatures increase no more than 2° Celsius (or 3.6° Fahrenheit) below pre-industrial levels²⁴¹—a goal now considered conservative by the global community.²⁴² His model produces higher damage estimates that are close to the Working Group’s average damage valuations.²⁴³

Opponents of climate mitigation policy frequently point to criticisms from Robert S. Pindyck, a noted climate economist who has been critical of the Working Group’s choice of damage functions. But as Professor Pindyck has himself stated, his “writings continue to be taken out of context by some to unfairly attack the Interagency Working Group’s methodology and its interim estimates.”²⁴⁴ While Professor Pindyck has questioned the shape of the models’ damage functions,²⁴⁵ he has acknowledged that the damage functions reflect “common beliefs” about the effects of two or three degrees of warming.

And Pindyck states that uncertainty about the social cost estimates, including the damage functions, “does not imply that [their] value should be set to zero until the uncertainty is resolved.”²⁴⁶ In fact, he actually advocates for an even higher social cost value than that produced by the Working Group,²⁴⁷ and has emphatically declared that “the federal government should continue to use the [Working Group’s] interim estimates . . . as lower bound

²³⁹ Richard S.J. Tol, *Why Worry About Climate Change?*, ESRI Research Bulletin 2009/1/1, at 3, 5 (2009).

²⁴⁰ See 2010 TSD, *supra* note 98, at 50 tbl.A5 (reporting that FUND model has the lowest mean estimate of the three models at all discount rates, including a negative social cost of carbon estimate at a 5% discount rate).

²⁴¹ The 2° C Limit on Global Warming, *The Economist* (Dec. 6, 2015), <https://www.economist.com/the-economist-explains/2015/12/06/the-2degc-limit-on-global-warming>.

²⁴² For instance, the Paris Agreement calls for governments to “hold[] the increase in the global average temperature to well below 2°C above pre-industrial levels and pursu[e] efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change.” Paris Agreement to the United Nations Framework Convention on Climate Change, Art. 2(1)(a), Dec. 12, 2015, T.I.A.S. No. 16-1104.

²⁴⁶ Robert S. Pindyck, Comments to Ms. Catherine Cook, Bureau of Land Management, on Proposed Rule and Regulatory Impact Analysis on Delay and Suspension of Certain Requirements for Waste Prevention and Resource Conservation 3 (Nov. 6, 2017), *available at* <https://perma.cc/8MY5-58P5>; see also Pindyck, *supra* note 245, at 16 (My criticism of IAMs should not be taken to imply that because we know so little, nothing should be done about climate change right now, and instead we should wait until we learn more. Quite the contrary.”).

²⁴⁷ Pindyck, *supra* note 244, at 1 (“My work instead strongly suggests that the estimates of the social cost of greenhouse gases should be higher than the February 2021 interim estimates[.]”) In 2019, Pindyck’s own estimate of the average social cost of carbon dioxide was between \$80 to \$100, with plausible values going up to \$200. Robert S. Pindyck, *The Social Cost of Carbon Revisited*, 94 J. ENV’T ECON. & MGMT. 140, 140, 154–55 (2019). This is far higher than the Working Group’s current central estimate of \$51.

estimates.”²⁴⁸ In other words, the best critic of the Working Group’s methodology that opponents could find *supports* continued use of the Working Group’s estimates and considers them to be conservative underestimates of the true cost to society of greenhouse gas emissions.

V. EPA Should Apply the Social Cost Estimates That It Has Developed Through 2070, and Coordinate With the Working Group to Adopt Climate-Damage Valuations Through at Least that Time Period

Although the Working Group’s latest guidance presents calculations of the social cost of greenhouse gases only through year 2050, the marginal damages caused by an additional ton of emissions will continue to rise over time after 2050.²⁴⁹ EPA has used the Working Group’s methodology to extend estimates of the social cost of greenhouse gases through year 2070.²⁵⁰ However, despite writing in the RIA that “Table 3-14 through Table 3-16 shows the combined total climate benefits expected to occur over 2023-2070,”²⁵¹ those tables’ titles suggest they only cover the years 2023-2050,²⁵² and all of EPA’s cumulative cost-benefit comparison tables similarly end in 2050.²⁵³

EPA does not give a clear reason why it stops its analysis in year 2050. As early as its 2009 analysis of vehicle emission standards, EPA had already been projecting the net benefits for its proposed vehicle standards through the year 2050,²⁵⁴ yet now, twelve years later, EPA has not extended its time frame any further. Notably, NHTSA has suggested that some model year 2029 vehicles could still be in service as late as 2068.²⁵⁵ And while regulated vehicles’ technology costs decline over the course of the analysis,²⁵⁶ many key benefits²⁵⁷—including climate benefits²⁵⁸—grow over the course of the analysis and may continue to grow after 2050. According to *Circular A-4*, EPA should select a time frame “long enough to encompass all the important benefits and costs likely to result from the rule.”²⁵⁹

EPA should urge the Working Group to adopt social cost of greenhouse gas estimates through at least 2070, if not further into the future, for all agencies to use as appropriate. EPA should identify how far into the future it believes the Proposed Rule will continue to generate

²⁴⁸ Pindyck, *supra* note 244, at 1.

significant costs or benefits. If the rule will have significant effects after 2050, EPA should either extend its time frame or else state its reasons for not doing so. If EPA is trying to match the time frame from the SAFE Rule, it could still include a longer time frame as a sensitivity analysis. If EPA lacks sufficient data to fully project costs and benefits beyond 2050, it should explain the data limitations. But given that costs are likely to decrease over time while benefits may continue into the distant future, EPA should state whether it believes that the net effects of stronger vehicle standards after 2050 will increase total net benefits. If so, this fact further highlights that EPA's cost-benefit projections, especially around climate benefits, are conservative, and that stronger vehicle emissions standards will deliver significant net benefits to society.

CONCLUSION

For the foregoing reasons, it is appropriate for EPA to continue to rely on the Working Group's valuations of the social cost of greenhouse gases in the Proposed Rule as conservative estimates. To bolster the legal justification for that reliance as it finalizes its regulation, EPA should provide additional explanation for its methodological choices and conduct additional sensitivity analysis around different social cost values.

Sincerely,
